Commander Naval Facilities Engineering Command Atlantic Division Norfolk, Virginia 23511-6287

Attention: Mr. Trueman Seamans Engineer-In-Charge

Subject: ADDENDUM TO REPORT OF UNDERGROUND FUEL INVESTIGATION AND COMPREHENSIVE SITE ASSESSMENT CAMP GEIGER FUEL FARM, MARINE CORPS BASE CAMP LEJEUNE, NORTH CAROLINA LAW ENGINEERING JOB NO. 475-08135-01

Dear Mr. Seamans:

In accordance with Naval Facilities Engineering Command Order for Supplies and Services Contract No. N62470-90-D-7625/0002 dated September 29, 1990, Law Engineering is pleased to present this addendum to the report of our environmental services for the above-referenced project site. The scope of our services, as described in the attached report, included drilling of three soil-test borings and collecting soil samples for chemical testing; installing three ground-water monitoring wells and collecting ground-water samples for chemical testing; performing an eight-hour aquifer test using the three newly-installed wells; and interpreting the data from the pump test to estimate the hydraulic characteristics of the aquifer.

This report is intended for the exclusive use of Naval Facilities Engineering Command, Atlantic Division. The contents should not be relied upon by any other parties without the express, written consent of Law Engineering. The findings are relevant to the dates of our site work and should not be relied upon to represent site conditions on other dates.

> 3301 ATLANTIC AVE. P.O. BOX 18288 RALEIGH, NC 27619 919-876-0416

We appreciate the opportunity to continue to work with you and the Navy on your environmental projects. If any questions arise, please contact us at (919) 876-0416.

Sincerely,

2

# **1.0 INTRODUCTION**

2

## 1.1 <u>Purpose of the Investigation</u>

On September 29, 1990, the Commander of the Atlantic Division Naval Facilities Engineering Command (LANTDIV) in Norfolk, Virginia, contracted with Law Companies Group, Inc. to perform a Comprehensive Site Assessment (CSA) at the Camp Geiger Fuel Farm, Marine Corps Base (MCB), Camp Lejeune, North Carolina (Drawing 1.1). The purpose of the investigation was 1) to identify the presence, magnitude and extent of possible free-product accumulation and ground-water contamination and 2) to assess potential exposure to subsurface contaminants resulting from the release(s) of petroleum fuels. As stated in Law Engineering's CSA Workplan dated July 25, 1991, the objective of the investigation was to provide sufficient data to meet the requirements of Sections 280.63 and 280.65 of 40 CFR Part 280, Federal Technical Standards for Underground Storage Tanks and Sections .0704 and .0706 of Title 15A, Chapter 2, Subchapter 2N, North Carolina Criteria and Standards Applicable to Underground Storage Tanks.

The assessment activities presented in the CSA Workplan were completed and a report, entitled "Final Report, Underground Fuel Investigation, Comprehensive Site Assessment", was issued to the Commander of the Atlantic Division, Naval Engineering Facilities Command on February 8, 1992. Based upon the results of the

initial assessment, it was determined that additional assessment was necessary to fully characterize the southern extent of petroleum contamination resulting from the underground fuel release and that performing an aquifer pumping test was necessary to estimate the hydraulic characteristics of the surficial aquifer.

#### 1.2 <u>Scope of Work</u>

Authorization to proceed with the investigation was granted by the Commander of LANTDIV of Norfolk, Virginia, via Addendum to Contract/Purchase Order No. N62470-90-D-7625/0002. As outlined in the contract, the scope of work included preparing a health and safety plan, advancing three soil borings, installing three monitoring wells, collecting and analyzing soil and ground-water samples, performing an eight-hour pumping test of the surficial aquifer, preparing an addendum to our report of investigation, and presenting our data and conclusions. Specific methods employed while performing the project activities are described in this report, which presents a summary of the additional assessment activities performed during October and November 1992.

# 2.0 SUBSURFACE CONTAMINATION ASSESSMENT

#### 2.1 Installation of the Monitoring Wells

Ξ

Law Engineering performed field activities on October 28 and 29, 1992, which consisted of advancing three soil borings. One of these borings was subsequently used to install pumping well 28 (PW-28). The remaining two borings were used to install monitoring wells 26 (MW-26) and MW-27, used as observation wells during the pumping test. The locations of these wells are shown on Drawing 3.1. The numbers of the drawings included in this addendum report correspond with those in our February 1992 report.

Law Engineering accomplished all drilling using hollow-stem augers and techniques described in ASTM D-1452. We steam-cleaned our down-hole drilling equipment prior to work at each drilling location. We used augers with an inside diameter of 6.25 inches for drilling each boring. The site geologist collected soil samples from each of the soil borings for field classification, headspace testing and chemical testing. We generally obtained soil samples for field classification at depths of 0 to 1.5 feet, 1.5 to 3 feet, 3 to 4.5 feet and on 5-foot centers thereafter to boring termination. We collected these soil samples with a split-spoon sampler 24 inches long and with an inside diameter of 1.375 inches (outside diameter of 2 inches). We obtained each soil

sample by continually dropping a 140-pound hammer for 30 inches, until the sampler was driven 18 inches into the substrate. We performed split-spoon sampling in general accordance with ASTM D-1586 and recorded on the field boring log the number of blows required to drive the sampler each 6-inch increment. After donning laboratory-grade gloves, we placed representative portions of each sample in two, pre-labeled plastic bags and sealed each bag for subsequent headspace testing.

The site geologist examined in the field the soil sample collected at each interval using visual/manual techniques described in ASTM D-2487 and ASTM D-2488. We classified the soil in general accordance with the United Soil Classification System. We have included a record of each test boring in Appendix A.

We collected one soil sample from the boring for the pumping well to test for grainsize distribution. We used the data from this test in calculations to estimate the hydraulic conductivity of the surficial aquifer. The results of this grain-size test are included in Appendix B.

The specifications for each soil boring included decontaminating the drilling equipment with a pressurized steam-cleaning unit, emplacing a silica-sand filter pack and a bentonite seal above the filter pack and grouting the well above the bentonite seal with a cement/bentonite slurry, and developing the well through low-yield pumping.

Development water was discharged to the oil/water separator which is located east of the fuel farm, as directed by activity personnel.

The screened intervals of the two observation wells are constructed of Schedule 40 PVC with an inside diameter of two inches. The screened interval of the pumping well is constructed of Schedule 40 PVC with an inside diameter of four inches. The risers for each of the three wells are constructed of Schedule 80 PVC. Each of the wells constructed by Law Engineering has a lockable cap and is protected by a flush-mount cover constructed of steel. Details for installing the monitoring wells are included in Appendix C. Upon installation, each well was developed through low-yield pumping. In Table 3.1, we have summarized the approximate volumes of water removed during well development and our observations of turbidity of the development water. The numbers of the tables included in this report correspond with those in our February 1992 report.

#### 2.2 Assessment of Soil Contamination

#### 2.2.1 Scanning Procedures

Law Engineering monitored all soil-investigation activities with an organic vapor analyzer (OVA) manufactured by Foxboro (Model 128) which had been calibrated

using methane. We used the OVA to qualitatively measure total volatile organics in the borehole, in ambient air, and in the individual soil samples. Values recorded with the OVA are qualitative and are not directly comparable to actual laboratory analytical results. However, the OVA is useful in providing a relative indication of the presence of volatile organics in soil samples.

2.2.2 Collection of Soil Samples

We collected soil samples from each boring for headspace testing and laboratory chemical analysis according to the following procedure:

- Drive the decontaminated split-spoon sampler to the desired depth interval.
- Retrieve and immediately open the split-spoon sampler. Quickly remove portions of sample aliquots from the split-spoon sampler and place the sample into two, pre-labeled, airtight plastic bags. Carefully execute sample handling in an effort to reduce the loss of the volatile organics. Seal and place the bags in a warm location.

- After approximately 10 minutes, test the headspace gas in one of the two bags with the OVA and record the peak value. This procedure was conducted for the soil sample collected at each sample-depth interval.
- From the soil samples collected from each boring, two samples were targeted for chemical testing. For those samples, the paired sample was transferred to a laboratory-supplied glass container, placed into a cooler, packed on ice and shipped to the laboratory for chemical analysis. Law Engineering maintained custody of the samples until shipment. Chain of custody forms are included in Appendix D.

2.2.3 Results of the Soil Sampling

A summary of headspace testing is presented in Table 4.1. Volatile organics were not detected in the boreholes for MW-26 and MW-27. Volatile organics were detected in excess of the equipment detection limit of 0.2 parts per million (ppm) in samples collected from the borehole for PW-28 at depths below the water table.

We have presented a summary of laboratory analyses of the soil samples collected from MW-26, MW-27 and PW-28 in Table 4.2. Copies of the laboratory test reports are included in Appendix E. The selected soil samples were tested for total petroleum

hydrocarbons (TPH) using EPA Methods 3550 (semi-volatiles) and 5030 (volatiles). The laboratory did not detect TPH in the soil samples collected from these three wells.

We have modified two of our isopleth maps (Drawings 4.3 and 4.3.1) to include the locations of MW-26, MW-27 and PW-28. TPH was not detected in the soil samples from these three wells; therefore, the contours on these isopleth maps did not change from those in our February 1992 report.

# 2.3 Assessment of Ground-Water Contamination

# 2.3.1 Procedures for Sampling the Monitoring Wells

Law Engineering installed three wells during the investigation to complement the 25 wells installed during previous investigations. Prior to sampling each of the three, newly-installed wells, Law Engineering measured and recorded the depth to ground water using an electronic, water-level probe. We recorded the data collected and observations made on the Monitoring Well and Sampling Field Data Worksheets (Appendix E). Ground-water elevations relative to sea level for the newly-installed wells are shown on the Monitoring Well Casing and Water Elevation Worksheet (Appendix F).

Law Engineering evacuated the newly-installed wells prior to collecting ground-water samples to remove stagnant water from the well casing and sand pack. We performed this task in an effort to collect samples representative of the water quality in the surficial aquifer. To evacuate the observation wells, we used decontaminated, Teflon bailers attached to new nylon cord; to evacuate the pumping well, we used an Arch Well Development Pump. We measured and recorded specific conductance, pH, and water temperature throughout the evacuation process. We generally evacuated the wells of at least three standing well volumes and until indicator parameters had stabilized.

Prior to sampling the wells, Law Engineering personnel donned laboratory-grade gloves. We collected the water samples and immediately decanted the samples from the bailer into pre-labeled sample containers. We sealed the containers, stored the containers in a chilled cooler, and maintained custody of the samples until shipment at the end of the day.

2.3.2 Results of the Ground-Water Sampling

2

We have presented a summary of laboratory analyses of the ground-water samples collected from all of the monitoring wells, including MW-26, MW-27 and PW-28, in Table 4.4. Copies of the laboratory test reports are included in Appendix H. We

tested the ground-water samples from MW-26, MW-27 and PW-28 for purgeable aromatic hydrocarbons by EPA Method 602, modified to include total xylenes and methyl tertiary butyl ether (MTBE). The laboratory did not detect constituents of petroleum hydrocarbons in the ground-water samples from MW-27 and PW-28. In the sample from MW-26, the laboratory detected total xylenes at a concentration of 1  $\mu$ g/L and MTBE at a concentration of 12  $\mu$ g/L. The North Carolina Ground-Water Quality Standard for total xylenes is 400  $\mu$ g/L and for MTBE is 50  $\mu$ g/L. Therefore, the concentrations of these constituents in MW-26 are below the state standards.

We have modified six isopleth maps from the February 1992 report (Drawings 4.7, 4.7.1 through 4.7.4 and 4.13) to include the locations of MW-26, MW-27 and PW-28. Benzene, toluene and ethylbenzene were not detected in the ground-water samples from these three wells; therefore, we did not change the contours for these constituents on the isopleth maps (Drawings 4.7.1, 4.7.2 and 4.7.3, respectively). We also did not change the contours of the isopleth maps of total xylenes concentrations (Drawing 4.7.4) and combined BTEX concentrations (Drawing 4.7). Since the concentration of 1  $\mu$ g/L of total xylenes detected by the laboratory in the ground-water sample from MW-26 is the same as the laboratory detection limit, it is possible that this concentration is a result of laboratory-induced contamination or handling of the samples during shipment.

Law Engineering documented MTBE at concentrations below the State Standard of 50  $\mu$ g/L in the ground-water sample from MW-26 and in the water collected during the pumping test performed on PW-28. MW-26 and PW-28 are hydraulically upgradient of the contaminant source at the Tank Farm; therefore, the MTBE documented in the ground water from these wells is possibly not related to activities at the Tank Farm. As we documented in our previous report, we also could not identify a likely source for the MTBE detected in the sample collected from MW-9, which is located west of the Tank Farm and of MW-26/PW-28. Because of the isolated occurrence of MTBE in several of the wells and no discernible pattern of contaminant migration, we are unable to offer an explanation as to other sources of MTBE.

#### 3.0 SITE HYDROGEOLOGY

#### 3.1 <u>Eight-Hour Pumping Test</u>

Law Engineering conducted an eight-hour pumping test during November 1992 at PW-28 to determine the performance characteristics of the well and to estimate the hydraulic parameters of the aquifer. Yield and drawdown were recorded so that the specific capacity of the well could be calculated. These data give a measure of the productive capacity of the well and provide information needed for the selection of

appropriately sized pumping equipment which may be necessary during the corrective action phase of the project. The pumping test also provided data from which to determine the transmissivity and storativity of the surrounding aquifer in order to predict the size and shape of capture zones produced during pumping of individual or multiple extraction wells.

3.1.1 Pumping-Test Procedures

Prior to the actual pumping test, PW-28 was pumped for approximately one hour to determine the approximate well yield. This "pre-test" data was necessary to select the proper size pump and to establish the pumping rate to be used during the test.

During the pumping test, the ground water pumped from PW-28 was stored in a tanker. The laboratory tested a water sample collected from this tanker for purgeable aromatics by EPA Method 602, modified to include total xylenes and MTBE. The discharged water was transported off the site by P&W Oil Company, which is storing the water for future disposal.

The eight-hour pumping test was conducted on November 4, 1992. During the test, a constant pumping rate of approximately 4.1 gallons per minute was maintained and the drawdown in each of the surrounding observation wells -- MW-22S, MW-26 and

MW-27 --- was measured and recorded at appropriate time intervals. These data are summarized in Appendix I. As summarized, after eight hours of pumping PW-28, approximately 2,360 gallons of ground water were extracted and drawdowns were as follows:

| Observation Well | Distance from PW-28 | Drawdown  |
|------------------|---------------------|-----------|
| MW-22S           | 113 feet            | 0.08 feet |
| MW-26            | 32 feet             | 0.22 feet |
| MW-27            | 88 feet             | 0.01 feet |

# 3.1.2 Estimating Aquifer Parameters

The data collected during the pumping test were used to calculate the storativity and transmissivity of the surrounding aquifer. These determinations were made by using type curve matching, time-downdown method, and the In-Situ computer software, TS-Match Theis Curve Automated Matching Program. TS-Match uses relative least-squares and the Newton-Raphson iterative method to solve the Theis solution, where:

$$s = \underline{O} \int_{u}^{\infty} \frac{e^{-u}}{nT} du,$$

<u>where</u>:

:

s= drawdown

Q = pumping rate, in gpm T = Transmissivity, in gpd/ft

 $u = (r^2S)/(4Tt)$ , where

- r = radial distance, in feet, from the pumped well to the observation well,
- S = storage coefficient, and

t= time

The TS-Match program makes the following assumptions:

- the production rate is constant.
- the aquifer is homogeneous, non-leaky, and there is no recharge.
- the aquifer has very large areal extent. If this is not the case, a mechanism has been provided to ignore data which the user considers are strongly influenced by the limited extent of the aquifer.
- water removed from storage is discharged instantaneously with decline in head (i.e., no delayed-yield effects).
- for analyzing production well data, skin (well loss) = 0.

for analyzing production well data, wellbore storage is not accounted for. However, a mechanism has been provided to ignore data that may be influenced by wellbore storage.

Ξ

In addition, the data were also analyzed manually by the type-curve matching method and the manual time-drawdown method to confirm the solution presented by TS-Match. We also analyzed grain-size distribution data from well PW-28 to estimate hydraulic conductivity. The field data and calculations are presented in Appendix I. The Type-curve matching, TS-Match, time-drawdown and grain size distribution solutions are as follows:

| SUMMARY OF AQUIFER PARAMETER ESTIMATIONS                                                                                                                              |                          |                         |       |  |  |  |  |

NOTES:

=

(1) MW-22 and MW-26 were used as observation wells for the pumping test.

(2) PW-28 was the well on which the pumping test was performed.

(3) Aquifer thickness is 22 feet, estimated from boring records in February 7, 1992, report.

(4) Grain-size distribution analysis not performed on soil samples from these wells.

From this data, average hydraulic conductivity values would be 169 ft/day for MW-22S, and 54 ft/day for MW-26. The hydraulic conductivity value from grain-size analysis for well PW-28, which is 99 ft/day, falls between these two other values. All three conductivity values fall within the same order of magnitude. The differences between the values may be explained by local heterogeneities in the soil matrix of the aquifer. A regional average of approximately 110 ft/day may be used for hydraulic conductivity in the surficial aquifer beneath the Fuel Farm area.

Similarly, average specific storage calculated from the pumping test ranges from  $10^{-3}$  to  $10^{-2}$ . Specific storage values associated with well MW-26 are higher than those

associated with MW-22. The differences may be explained by local heterogeneities in the soil matrix of the aquifer.

## 4.0 PROCEDURES FOR QUALITY CONTROL

#### 4.1 <u>Decontaminating Equipment</u>

The CSA Workplan details the quality-control procedures followed for handling and decontaminating equipment in the field. Using the procedures described in the Workplan, we decontaminated our drilling equipment adjacent to the oil/water separator, which is located east of the Fuel Farm.

#### 4.2 <u>Collecting, Handling and Shipping Samples</u>

The CSA Workplan details the quality-control procedures followed for collecting, handling and shipping samples. We utilized rinse blanks and trip blanks as qualitycontrol measures to provide checks on the integrity and quality of our ground-water sampling program.

Law Engineering submitted an equipment rinse blank to the laboratory to evaluate the procedures we used for decontaminating the Teflon bailers. Law Engineering also

submitted a trip blank to the laboratory to check the integrity of the sample containers, to determine if contaminants may have entered the sample containers during shipment to and from the job site, and to check for laboratory-induced contamination. Each of the blanks was analyzed for purgeable aromatics. The two blank samples did not contain contaminant levels above the laboratory detection limit. Although, our procedures for bailer decontamination were generally successful in eliminating the introduction of contaminants through the sampling equipment, it is possible that the 1  $\mu$ g/L of total xylenes documented in the ground-water sample from MW-26 may have resulted from incomplete decontamination of the bailer used to sample that well or from laboratory-induced contamination.

APPENDIX D INTERIM REMEDIAL ACTION REMEDIAL INVESTIGATION (BAKER, 1994)

# Final

## Interim Remedial Action Remedial Investigation/ Feasibility Study

## Operable Unit No. 10 Site 35 - Camp Geiger Area Fuel Farm

Marine Corps Base Camp Lejeune, North Carolina

**Prepared For:** 

Department of the Navy Atlantic Division Naval Facilities Engineering Command Norfolk, Virginia

Under the

### LANTDIV CLEAN Program

Comprehensive Long-Term Environmental Action Navy

#### **EXECUTIVE SUMMARY**

### **Introduction**

An Interim Remedial Action Remedial Investigation (RI) was conducted at Operable Unit 10, Site 35 - Camp Geiger Area Fuel Farm to provide additional data regarding petroleum hydrocarbon contaminated soil to support the selection of an interim remedial action. Previous investigations had determined the presence of fuel-related contamination in subsurface soils and shallow groundwater in the vicinity of the Fuel Farm. Based on previously obtained data and reports of fuel-like odors along Brinson Creek by Camp Lejeune, LANTDIV, and Baker personnel, an Interim Remedial Action RI and Feasibility Study (FS) was deemed necessary because it was determined qualitatively that:

- The existing site conditions potentially expose nearby human populations, animals, or food chains to toxic substances, pollutants, or contaminants; and
- High levels of toxic substances or pollutants in soils are largely at or near the surface that may migrate.

### Site Location and Description

Camp Geiger is located at the extreme northwest corner of MCB, Camp Lejeune, Onslow County. The main entrance to Camp Geiger is off U.S. Route 17, approximately 3.5 miles southeast of the City of Jacksonville, North Carolina. Site 35, the Camp Geiger Area Fuel Farm refers primarily to five, 15,000-gallon aboveground storage tanks (ASTs), a pump house, and a fuel unloading pad situated within Camp Geiger just north of the intersection of Fourth and "G" Streets.

#### Site History

Construction of Camp Geiger was completed in 1945, four years after construction of MCB, Camp Lejeune was initiated. Originally, the Fuel Farm ASTs were used for the storage of No. 6 fuel oil, but, were later converted for storage of other petroleum products including unleaded gasoline, diesel fuel, and kerosene. The date of their conversion is not known. Routinely, the ASTs at Site 35 supply fuel to an adjacent dispensing pump. A leak in an underground line at the station was reportedly responsible for the loss of roughly 30 gallons per day of gasoline over an unspecified period (Law, 1992). The leaking line was subsequently sealed and replaced.

The ASTs at Site 35 are currently used to dispense gasoline, diesel and kerosene to government vehicles and to supply USTs in use at Camp Geiger and the nearby New River Marine Corps Air Station. The ASTs are supplied by commercial carrier trucks which deliver product to fill ports located on the fuel unloading pad at the southern end of the facility. Six, short-run (120 feet maximum), underground fuel lines are currently utilized to distribute the product from the unloading pad to the ASTs. Product is dispensed from the ASTs via trucks and underground piping.

Reports of a release from an underground distribution line near one of the ASTs date back to 1957-58 (ESE, 1990). Apparently, the leak occurred as the result of damage to a dispensing pump. At that time the Camp Lejeune Fire Department estimated that thousands of gallons of fuel were released although records of the incident have since been destroyed. The fuel reportedly migrated to the east and northeast toward Brinson Creek. Interceptor trenches were excavated and the captured fuel was ignited and burned.

Another abandoned underground distribution line extended from the ASTs to the former Mess Hall Heating Plant, located adjacent to "D" Street, between Third and Fourth Streets. The underground line dispensed No. 6 fuel oil to a UST which fueled the Mess Hall boiler. The Mess Hall, located across "D" Street to the west, is believed to have been demolished along with its Heating Plant in the 1960s.

In April 1990, an undetermined amount of fuel had been discovered by Camp Geiger personnel along the unnamed drainage channels north of the Fuel Farm. Apparently, the source of the fuel, believed to diesel or jet fuel, was an unauthorized discharge from a tanker truck that was never identified. The Activity reportedly initiated an emergency clean-up which included the removal of approximately 20 cubic yards of soil.

The Fuel Farm is scheduled to be decommissioned in 1994. Plans are currently being prepared to empty, clean, dismantle, and remove the ASTs along with all concrete foundations, slabs on grade, berms and associated underground piping. The Fuel Farm is being removed to make

ES-2

way for a four lane divided highway proposed by the North Carolina Department of Transportation (NCDOT).

#### **Previous Investigations and Findings**

Previous investigations include an Initial Assessment Study (Water and Air Research [WAR], 1983), a Confirmation Study (Environmental Science and Engineering, Inc. [ESE], 1984 and 1987), a Focused Feasibility Study (NUS Corporation [NUS], 1990), and a Comprehensive Site Assessment (Law Engineering, Inc. [Law], 1991).

The Initial Assessment Study identified Site 35 as one of 23 sites warranting further investigation. Environmental media were not sampled as part of this study.

ESE performed the Confirmation Study at the Fuel Farm between 1984 and 1987. Soil, groundwater, surface water, and sediment samples were obtained and analyzed for lead and oil and grease. Groundwater was also analyzed for volatile organics. Oil and grease results indicated that soils northeast of the Fuel Farm were potentially impacted by site activities.

Additional wells were installed by NUS Corporation during the Focused Feasibility Study, which was conducted in 1990. Soil cuttings obtained from two of the four well boreholes contained hydrocarbon related contamination.

Law conducted the Comprehensive Site Assessment in 1991. A total of 18 soil borings were drilled, sampled and converted to nested wells that monitor the water table aquifer at two depths. An additional three soil borings were drilled to provide stratigraphic data. Five more soil borings were drilled to provide data regarding vadose zone contamination. Nine handauger samples were also obtained. A follow-up study was conducted subsequent to the Comprehensive Site Assessment. Three additional borings were drilled, sampled and converted to wells.

Law identified areas of impacted soil and groundwater directly beneath and apart from the Fuel Farm. The nature of the contamination included both chlorinated organic compounds (e.g., TCE, trans-1,2-DCE, and vinyl chloride) and petroleum hydrocarbons (e.g., TPH, MTBE, BTEX). The majority of the soil contamination encountered appeared to be associated with a fluctuating groundwater table. Two plumes of shallow groundwater contaminated with petroleum constituents and two plumes contaminated with chlorinated organics were

identified. All four plumes were located north of Fourth Street and east of E Street except for a portion of a TCE plume extending southwest of Fourth Street.

The Interim Remedial Action RI conducted by Baker in 1993 and 1994 consisted of drilling seven additional soil borings including five in those areas where groundwater contamination plumes were suspected. A single soil sample was obtained from each of these soil borings and analyzed for TCL organics, TAL inorganics, TPH and oil and grease. Samples obtained from two boring locations (SB-30 and SB-34) displayed relatively high concentrations of benzene, toluene, ethylbenzene, xylenes, naphthalene and 2-methylnaphthalene; constituents commonly associated with fuels. These two locations also displayed the highest detected concentrations of TPH encountered during the Interim Remedial Action RI. Highest detected concentrations of these contaminants were in samples taken at or below the shallow water table.

The non-fuel related contaminant trichloroethene (TCE) was detected at concentrations below its corresponding contract required quantitation limit in two samples. One of these samples was obtained from background soil boring location SB-29.

(

In addition to soil boring samples a total of ten shallow soil samples were obtained in the vicinity of Brinson Creek and the unnamed drainage channels located to the north of the Fuel Farm. No significant levels of fuel-related contaminants and TPH were detected in these samples. Oil and grease was, however, detected in these shallow soil samples. Therefore, two additional samples were obtained approximately 1/2-mile upstream of the site along Brinson Creek to establish background levels of oil and grease. Background oil and grease results obtained upstream of Site 35 indicate that naturally-occurring organics in soils or an upgradient contamination source could be responsible for the positive oil and grease results obtained at the site. An additional sample was also obtained downstream of the site to identify the potential extent of contamination.

In general, the Interim Remedial Action RI data confirm the findings of the CSA (Law, 1992) that indicated contaminated soil conditions at Site 35 are primarily associated with a fluctuating shallow groundwater plume. Contamination encountered in the vicinity of monitoring wells MW-21 and MW-25 was detected at approximately two or more feet above the measured groundwater surface and may be indicative of contamination-not associated with a fluctuating groundwater plume. To date, however, recorded groundwater levels

provide insufficient data to afford an estimate of the range of groundwater elevation fluctuation at Site 35.

#### Nature and Extent of Contamination

Petroleum hydrocarbon contamination at Site 35 is primarily associated with shallow groundwater that is typically encountered across the site at six to eight feet below the ground surface (bgs). Law identified two distinct petroleum hydrocarbon shallow groundwater plumes including one directly beneath the Fuel Farm ASTs and another located immediately northwest of the Fuel Farm ASTs in the vicinity of the unnamed drainage channels that covey surface runoff to Brinson Creek.

In addition to contaminated groundwater samples, subsurface soil samples have been identified at the site as contaminated with petroleum hydrocarbons. The contaminated soil samples, for the most part, were obtained along a narrow zone that extends about one to two feet above the groundwater table (as measured on two separate occasions including once in August, 1991 by Law and again in March, 1994 by Baker). The soil contamination in this zone just above the top of shallow groundwater appears to have been transported there by a fluctuating groundwater table. In only two areas did the results of soil sampling indicate the presence of elevated petroleum hydrocarbon contamination at locations sufficiently above the top of groundwater such that the source of the contamination may not have been a fluctuating groundwater table. The two areas are both located north of the Fuel Farm where past unauthorized discharges of fuel products were reported to have occurred and are centered around samples obtained from monitoring well MW-25 and monitoring well MW-21, respectively.

#### Summary of Site Risks

A preliminary baseline risk assessment, limited to Site 35 soil contamination, was conducted using data from the previous investigations and the Interim Remedial Action RI. A more comprehensive baseline risk assessment involving groundwater, surface water, and sediment, in addition to soil, will be conducted as part of the comprehensive Site 35 Remedial Investigation being conducted concurrently.

Because soil contamination is associated with subsurface soils at or below the water table, a construction worker scenario was used to determine potential human health risks.

The construction worker was assumed to engage in excavation activities and could potentially contact contaminants in deep soil by dermal contact, through accidental ingestion and by inhaling contaminant-laden dust particles. A construction worker scenario is the most likely current potential human receptor as well as the most likely future receptor because of the new highway construction scheduled for Site 35. Benzene and arsenic were retained as chemicals of potential concern (COPCs) for quantitative evaluation in the preliminary baseline risk assessment. An incremental lifetime cancer risk (ICR) value of  $3 \times 10^{-6}$  was derived for the construction worker. This value falls within USEPA's target risk range of  $10^{-6}$  to  $10^{-4}$  which is generally considered to be acceptable by the Agency. Noncarcinogenic hazard index (HI) values fell below 1.0 suggesting that systemic adverse health effects would not occur subsequent to exposure.

An ecological risk assessment was not performed at this time because soil contaminants are encountered at depths 4 feet below the ground surface or more and occur primarily at or below the shallow water table. A comprehensive baseline ecological risk assessment, in addition to the baseline human health risk assessment, will, however, be conducted as part of the concurrent comprehensive Remedial Investigation at Site 35.

In addition to human health risks, North Carolina's Department of Environment, Health and Natural Resources Division of Environmental Management's Site Sensitivity Evaluation (SSE) was performed. SSE cleanup goals for gasoline, diesel and oil and grease were derived. Cleanup goals of 40 mg/kg, 160 mg/kg and 800 mg/kg, respectively, were calculated. The applicability of the SSE cleanup goals will be further addressed in the Interim Remedial Action Feasibility Study (FS).
