Ecological Risk Assessment for Operable Unit No. 2 (Sites 6, 9, and 82)

Marine Corps Base, Camp Lejeune, North Carolina

Prepared For:

Department of the Navy Atlantic Division Naval Facilities Engineering Command Norfolk, Virginia

Under the

LANTDIV CLEAN Program

Comprehensive Long-Term Environmental Action Navy

EXECUTIVE SUMMARY

INTRODUCTION

Marine Corps Base (MCB), Camp Lejeune, North Carolina was placed on the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) National Priorities List (NPL) that became effective on October 4, 1989 (54 Federal Register 41015, October 4, 1989). The United States Environmental Protection Agency (USEPA) Region IV, the North Carolina Department of Environment, Health and Natural Resources (NC DEHNR) and the United States Department of the Navy (DoN) then entered into a Federal Facilities Agreement (FFA) for MCB Camp Lejeune. The primary purpose of the FFA was to ensure that environmental impacts associated with past and present activities at the MCB were thoroughly investigated and appropriate CERCLA response/Resource Conservation and Recovery Act (RCRA) corrective action alternatives were developed and implemented as necessary to protect public health and the environment.

The Fiscal Year 1994 Site Management Plan for MCB Camp Lejeune, a primary document identified in the FFA, identifies 27 sites requiring Remedial Investigation/Feasibility Study (RI/FS) activities. These 27 sites have been divided into thirteen operable units to simplify proceeding with RI/FS activities. This report describes the RI conducted at Operable Unit (OU) No. 2, which is comprised of Sites 6, 9, and 82.

SITE DESCRIPTION

OU No. 2 is located approximately 1.75 miles east of the New River and 2 miles south of State Route 24 on the mainside portion of MCB Camp Lejeune. The unit is bordered by Holcomb Boulevard on the west, Sneads Ferry Road on the south, Piney Green Road on the east, and by Wallace Creek on the north boundary. Camp Lejeune Railroad operates rail lines parallel to Holcomb Boulevard bordering OU No. 2. OU No. 2 covers an area of approximately 210 acres. OU No. 2 consists of three sites: Sites 6, 9, and 82.

There are distinctive areas of concern within each site of OU No. 2. The following section describes the background of each site.

Site 9

Site 9 is referred to in this report as the "Fire Training Area" (the formal name, as provided in the FFA, is "Fire Fighting Training Pit at Piney Green Road"). The site covers an area of approximately 2.6 acres. Site 9 is bounded by Holcomb Boulevard on the west, Bear Head Creek approximately 500 feet to the north, Piney Green Road on the east and Sneads Ferry Road on the south. Site 6 also borders Site 9 to the north. Locally, the site is bounded by unnamed streets leading to various storage buildings in the vicinity. Site 9 consists of an asphalt-lined fire training pit, an oil/water separator, four aboveground storage tanks (ASTs), and a fire tower (smoke house). The fire training pit, located in the southern area of the site, is used to conduct training exercises for extinguishing fires caused by flammable liquids. The oil/water separator is located next to the fire training pit to collect water used in the training exercises and storm water that falls into the pit. The recovered product collected in the oil/water separator is disposed of off site. Two of the ASTs at Site 9 are 2500-gallon steel tanks labeled "DO NOT USE". These tanks are not currently in use. Two additional storage tanks are located in a bermed area. These tanks are constructed of steel and contain approximately 500 gallons each.

Site 6

Site 6 is located north of and adjacent to Site 9. Site 6 is bounded on the north by Site 82, by Piney Green Road on the east, by Site 9 on the south, and by Holcomb Boulevard on the west. Site 6 covers an area of approximately 177 acres that incorporates Storage Lots 201 and 203, the wooded area between the storage lots, and a ravine, which begins at Site 6 and bisects Site 82. Three surface water bodies are associated with Site 6 for the purpose of this RI: Wallace Creek, Bear Head Creek, and a ravine located in the wooded area north of Lot 203 that drains to Wallace Creek.

Open Storage Lot 201 (Lot 201) is a fenced lot located in the south-central portion of Site 6. It is a flat area with sparse vegetation around the fence lines. The lot is approximately 25 acres in size. It is currently being used for the storage of military vehicles and equipment, lumber, hydraulic oils and lubricants, non-PCB transformers, and other supplies (ESE, 1991).

Open Storage Lot 203 (Lot 203) is a fenced lot located in the northern portion of Site 6 covering approximately 46 acres. Lot 203 is a relatively flat area with elevation differences of approximately five feet. The ground surface is comprised of both naturally existing soil and

ES-2

fill material. Lot 203 is bordered by Site 82, Piney Green Road to the east, woods to the south, and by Holcomb Boulevard to the west. Lot 203 is currently inactive.

Approximately 40 55-gallon drums are present at Lot 203. The majority of the drums, if labeled, were identified as containing lubricants, petroleum products, or corrosives. Empty storage tanks were also found on Lot 203. They were labeled as containing diesel fuel, gasoline, and kerosene (Baker, 1992).

A ravine is located in the northwest section of Site 6. The steepest area of the ravine is located "inside" of Storage Lot 203. The banks of the ravine gradually decline as the ravine bisects Site 82. The elevation ranges from 25 feet above msl at the north boundary of Lot 203 to 5 feet above msl where the ravine drains into Wallace Creek. The surface of the ravine area is littered with various debris including batteries, fencing, tires, empty unlabeled drums, wire cables, commercial ovens, commodes, and respirator cartridges. An empty drum labeled "DDT" was also found in the ravine area, as were small canisters labeled to contain "DDT".

Woods and open fields surround both Storage Lots 201 and 203 and make up the remaining area of Site 6. The topography of the wooded areas is relatively flat, but localized trenching and mounding is visible just north of Lot 203 and west of Piney Green Road. The wooded areas are randomly littered with debris including spent ammunition casings, and empty or rusted drums. Markings were observed on a few drums (most drums did not contain marking due to their condition and age) located north of Lot 203. These drums were marked as "lubrication oils". Many of the drums observed were only shells or fragments of drums. (Baker, 1992)

Site 82

Site 82 is situated at the northern end of OU No. 2. It is bordered to the north by Wallace Creek, to the east by Piney Green Road, to the west by Holcomb Boulevard, and to the south by Site 6. Site 82 encompasses approximately 30 acres and is predominantly covered by woodlands. The site is randomly littered with debris including communication wire, spent ammunition casings, and empty or rusted drums. Markings were observed on a few drums, however, most of the drums did not contain markings due to their condition and age. Some of the drums were marked as "lubrication oil" and "anti-freeze".

The topography within Site 82 is relatively flat near the southern portion of the site, but becomes very steep near the bank of Wallace Creek. Localized trenching and mounding is

visible near the southern portion of the site. The ravine bisects the site, as shown on Figure 1-3.

SITE HISTORY

Site 9

Site 9 has been used as a fire fighting training area from the early 1960s to the present. Fire extinguishing activities took place in an unlined pit. In 1981 the pit was lined with asphalt. The training fires in the pit were started with used oil, solvents, and contaminated fuels (unleaded). Approximately 30,000 to 40,000 gallons of JP-4 and JP-5 fuel were also burned in the fire training pit (Baker, 1992).

Site 6

Site 6 has a long history of various uses including the disposal and storage of wastes and supplies. This discussion on the history of Site 6 has been broken down into Storage Lot 201, Storage Lot 203, and the wooded areas and ravine to simplify the historical descriptions of these areas.

Currently, Lot 201 is used to store military equipment, vehicles, hydraulic oils, and other "non-hazardous" supplies. Pesticides were reportedly stored in the northeast and southeast corners of the lot. Transformers containing PCBs were reportedly stored in the southwest corner of the lot (Water and Air Research, 1983).

Lot 203 has been used as a disposal area since the 1940s. There is little documentation on the disposal activities at this lot. Lot 203 in not currently active as a storage or disposal area, but the ground surface is littered with various debris. Lot 203 was also used for the storage and disposal of radio and communication parts, shredded tires, lubricants, petroleum products, corrosives, expended demolition kit training materials, ordnance, sheet metal debris, wire cables, and wooded pallets. Empty and full 55-gallon drums were found at various locations on Lot 203.

Lot 203 is currently fenced. From historical photographs, it appears that the fenced boundaries have changed since the lot was in operation. Former employees at Lot 203 have

reported disposal of various chemicals including PCBs, cleaning solvents, electrolytes from used batteries, and waste oils.

The surface of the wooded areas around Lots 201 and 203 is randomly littered with debris including drums, metal storage containers, and spent ammunition cartridges. No organized disposal operations are documented for the wooded areas. A ravine is located on the northern boundary of Lot 203. As previously stated, this area is currently littered with various debris. From the deposition of the debris in the ravine, it appears that trucks may have dumped their contents into the ravine from Lot 203.

PREVIOUS INVESTIGATIONS

During the period 1983 through 1991, various studies were conducted at Sites 6, 9, and 82 by the Department of the Navy. These studies included an Initial Assessment Study and a Confirmation Study under the DoN's Installation Restoration Program. The studies included soil investigations at Site 6 (Lots 201 and 203), groundwater investigations at Sites 6, 9, and 82 and surface water/sediment investigations at Wallace Creek and Bear Head Creek.

Soil samples collected from shallow borings at Lot 201 and 203 were analyzed for pesticides. Low levels of pesticides ranging in concentration from 1.3 µg/kg to 770 µg/kg were detected in almost all of the soil samples. Groundwater samples collected from eight shallow monitoring wells at Site 6 revealed low levels of volatile organic compounds such as carbon disulfide and chloromethane in well 6GW6, which is located to the east of Lot 201. In addition, low levels of benzene and 1,1,2,2-tetrachloroethane were detected in well 6GW1, which is located just north of Lot 203. Further investigation of nearby water supply wells revealed elevated levels of trichloroethene (TCE), vinyl chloride, 1,2-dichloroethene, and tetrachloroethene (PCE) in wells HP-651 and HP-653. These wells are located east of Piney Green Road near Lot 203. The supply wells are screened to a depth of approximately 200 feet. The wells are no longer in operation due to elevated volatile organic compounds (VOCs).

Three shallow monitoring wells were installed at Site 9. Groundwater samples were collected in 1984, 1986, and 1987. In addition, one sample was collected in 1984 from a nearby supply well. No contamination was detected in the supply well. Low levels of phenol were detected in all three shallow monitoring wells. In addition, low levels of lead and chromium were detected in all three wells. Upstream and downstream surface water samples were collected from Wallace Creek and Bear Head Creek. Surface water samples collected from Wallace Creek revealed elevated levels of VOCs such as TCE, vinyl chloride, and 1,2-dichloroethene. No organic contamination was detected in Bear Head Creek. Sediment samples collected from Bear Head Creek revealed low levels of pesticides (13 to 75 μ g/kg) both upstream and downstream from Site 6. No pesticides were detected in either sample collected from Wallace Creek. However, PAHs (1,990 μ g/kg total) were detected in the downstream sediment sample collected near Holcomb Boulevard.

<u>Site 82</u>

A site investigation was conducted at Site 82 in June, 1991 by Halliburton NUS Environmental Corporation (NUS). The investigation was initiated based on results from an Environmental Science and Engineering (ES&E) field investigation in 1986 (the investigation was conducted as part of a study for Site 6). During this investigation, surface water samples collected from Wallace Creek contained VOCs. It was determined that the source of the VOCs in Wallace Creek most likely did not originate from Site 6 (Lot 203). Subsequently a new site, Site 82, was created to investigate the source of the VOCs (NUS, 1992).

The investigation conducted by NUS consisted of installing six shallow soil borings and three shallow monitoring wells, soil and groundwater sampling, and surface water and sediment sampling (Wallace Creek). Results from the investigation indicated positive detections of organic contamination in all of the media sampled. Pesticides (4,4'-DDD, 4,4'-DDE, 4,4'-DDT, endosulfan II, and dieldrin) were detected in soil (33 to 110 μ g/kg) and sediment (12 to 69 μ g/kg) samples with lower levels in surface water and groundwater. PCB (PCB-1260 and PCB-1242) contamination was also present in soil (150-1,900 μ g/kg), groundwater (15 μ g/l), surface water (80 μ g/l), and sediments (220-700 μ g/kg). Further, levels of TCE (3 to 74 μ g/l), 1,2-dichloroethene (6 to 64 μ g/l), and vinyl chloride (11 μ g/l) were detected in surface water samples. Note that concentrations of VOCs were not detected in any of the wells sampled.

REMEDIAL INVESTIGATION ACTIVITIES

A Remedial Investigation (RI) was conducted at Operable Unit No. 2 beginning in August 1992 (Final Project Plans were submitted in May 1992). The RI focused on various areas of concern within Operable Unit No. 2 including: Lot 201, Lot 203, the wooded areas surrounding both storage lots, the ravine north of Lot 203, Site 9, Site 82, Wallace Creek, and Bear Head Creek. Moreover, the investigation was conducted in two phases of work: Phase I (August through November 1992) and Phase II (February through May 1993).

The soil investigation focused the reported disposal areas within Lot 201 and Lot 203. Sampling grids were established at the following areas:

- Two reported pesticide storage areas within Lot 201
- A reported PCB storage area within Lot 201
- A reported pesticide disposal area within Lot 203
- A reported PCB disposal area within Lot 203

In addition, the soil investigation focused on other portions of OU No. 2 that were determined to be environmental concerns based on site reconnaissances and review of historical photographs. Sampling grids were established at the following areas:

- The wooded areas to the north, east, and south of Lot 201
- Site 82
- The fenced-in portion of Lot 203
- The ravine north of Lot 203

Two sampling grids were also established at Site 9 to evaluate potential soil contamination. The grids were established at:

- The fire training pit and oil/water separator
- Aboveground storage tanks

The grid points were surveyed by a licensed surveyor prior to initiating the soil investigation. Shallow borings were augered at each grid point and soil samples were collected at 2-foot continuous intervals until the water table was encountered. The majority of the samples were analyzed for full Target Compound List (TCL) organics and Target Analyte List (TAL) inorganics. In areas where a certain contaminant was expected based on existing information (e.g., pesticide disposal area at Lot 203), the majority of samples were analyzed for a particular contaminant of concern (e.g., TCL pesticides); however, at least ten percent of samples collected from these areas were analyzed for full TCL organics and TAL inorganics. The groundwater investigation focused on evaluating surficial and deep groundwater quality at Operable Unit No. 2. Shallow wells were installed in the wooded areas, Site 82 Lot 201, Lot 203, and Site 9. Deep groundwater wells were installed at Site 9, Lot 201, Lot 203, and Site 82. Groundwater samples were analyzed for full TCL organics and TAL inorganics (total and dissolved metals analysis). Furthermore, two rounds of samples were collected from the Phase I and existing wells, and one round of samples were collected from the Phase II wells. The groundwater investigation also included three to four rounds of water level measurements. These measurements included staff gauges that were installed in Bear Head Creek and Wallace Creek.

Placement of monitoring wells was based on reported storage/disposal areas, results of a geophysical investigation conducted at Lot 203, and review of historical aerial photographs produced by the U.S. Environmental Protection Agency (EPA) Environmental Photographic Interpretation Center (EPIC). Additionally, the placement of the Phase II shallow wells were based on the results of a soil gas survey and placement of the Phase II deep wells were based on the results of the Phase I analytical results.

Surface water and sediment investigations were conducted in Bear Head Creek, Wallace Creek, and the ravine. Surface and subsurface sediment samples were collected from the middle portion of the stream as well as from the stream bank. Deep surface water samples were collected when the depth of water exceeded five feet. All samples were analyzed for full TCL organics and TAL inorganics.

In addition to these studies, an ordnance survey was required at Lot 203 and the wooded areas surrounding Lot 203 due to the presence of surface and subsurface unexploded ordnance (UXO). On two occasions, the MCB Camp Lejeune ordnance specialists were contacted to examine UXO. In both cases, the devices were not determined to present a hazard.

Ecological Risk Assessment

Baker Environmental conducted an Ecological Risk Assessment (ERA) for Operable Unit No. 2 (Sites 6, 9 and 82) in accordance with the scope of work identified under Task 6 in the Final Remedial Investigation/Feasibility Study Work Plan (May 1992), prepared by Baker Environmental, Inc. (Baker), under Contract Task Order (CTO) 0133. The ERA has been conducted in conjunction with a remedial investigation/feasibility study (RI/FS) at Operable Unit No. 2 (OU No. 2) under the Department of Navy's Comprehensive Long-Term Environmental Action - Navy (CLEAN) Program, Contract N62470-89-D-4814. The RI and FS documents have been submitted under a separate cover.

The objective of the ERA is to determine if past reported disposal practices at OU No. 2 are adversely impacting the ecological integrity of the terrestrial environment and of Wallace Creek, Bear Head Creek, or the ravine. This assessment also evaluated the potential effects of contaminants at OU No. 2 on sensitive environments including wetlands, protected species, and fish nursery areas. The conclusions of the ERA will be used in conjunction with the human health risk assessment in order to determine the appropriate remedial action at this site for the overall protection of public health and the environment.

The ERA evaluated and analyzed the results from the remedial field investigation conducted as part of CTO 0133 and historical data collected during previous studies. The remedial field investigations included sampling and chemical analysis of the surface water, sediments, soil, and groundwater. In addition, ecological field investigations were conducted including collecting fishes for population statistics and chemical analysis of their tissues; collecting benthic macroinvertebrates for population statistics; and collecting blue crabs for chemical analysis of their tissues. Finally, information used to evaluate sensitive environments was obtained from historical data and previous studies conducted at Marine Corps Base (MCB) Camp Lejeune, North Carolina.

This assessment also evaluated the potential effects of contaminants at OU No. 2 on sensitive environments including wetlands, protected species, and fish nursery areas. Information for these environments were obtained primarily from historical data and previous studies conducted at MCB Camp Lejeune.

Conclusions

The following sections contain the summary/conclusions for the ERA including water quality, sediment quality, surface soil quality, fish, benthic macroinvertebrates and terrestrial fauna.

Water Quality

The water quality summary/conclusions are discussed in the following sections.

Wallace Creek

None of the TCL organic COCs detected in Wallace Creek exceeded applicable water quality criteria values. Dissolved oxygen concentrations and pH values were below WQS and WQSV at some of the stations, but probably were associated with natural conditions.

As detailed below, the surface water concentrations of cadmium, copper, lead, mercury, nickel, silver, and zinc exceeded the North Carolina Water Quality Standards (WQS) and/or U.S. EPA Region IV acute or chronic Water Quality Screening Values (WQSV) in some of the samples. Nickel, copper, and mercury exceeded standards in sampling stations upstream, adjacent, and downstream of Site 6 and 82. Cadmium and silver exceeded standards at one adjacent station. Whereas, lead concentrations exceeded standards at one station upstream to Sites 6 and 82. Zinc was exceeded in one upstream and one downstream station to Sites 6 and 82.

In addition, several TAL inorganics had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in Wallace Creek to be adversely affected by chronic toxicity from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represents long-term conditions.

Bear Head Creek

None of the TCL organic COCs detected in Bear Head Creek exceeded applicable water quality criteria values. Dissolved oxygen concentrations and pH values were below WQS and WQSV at some of the stations, but probably were associated with natural conditions.

Surface water concentrations of copper, lead, mercury, nickel, and silver exceeded the WQS and/or WQSV in some of the samples. Copper, nickel, and silver concentrations exceeded standards at one downstream station. Whereas, mercury concentrations exceeded standards at two downstream stations. Lead exceeded standards at one immediately downstream and one immediately upstream station to Sites 6 and 9.

In addition, several TAL inorganics had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in Bear Head Creek to be adversely affected by chronic toxicity

from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represents long-term conditions.

<u>Ravine</u>

None of the TCL organic COCs detected in the ravine exceeded applicable water quality criteria values.

Surface water concentrations of aluminum, cadmium, copper, iron, lead, silver, and zinc exceeded the WQS and/or WQSV in some of the samples. Aluminum and lead concentrations exceeded standards in the samples from the northern section of Site 6 through Site 82. Zinc concentrations were exceeded at one station within Site 6 and several stations throughout Site 82. Aluminum and zinc concentrations were higher at the southern stations within Site 82. Iron exceeded standards at two stations in the northern ravine area of Site 82. Cadmium concentrations exceeded standards in one ravine station in Site 6 and one in Site 82. Copper exceeded standards at one station in Site 6 and three stations in Site 82. Silver exceeded surface water standards at stations throughout Site 82.

In addition, several TAL inorganics had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in the ravine to be adversely affected by chronic toxicity from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represents long-term conditions.

Pettiford Creek

Dissolved oxygen concentrations were below the WQS at one station, but probably was associated with natural conditions.

Sediment Quality

Currently promulgated sediment quality criteria do not exist. Until these criteria are developed, Region IV is using sediment values compiled by NOAA as screening values for evaluating the potential for chemical constituents in sediments to cause adverse biological effects (USEPA, 1992b). The lower ten percentile (Effects Range-Low (ER-L)) and the median percentile (Effects Range-Median (ER-M)) of biological effects have been developed for several

of the chemicals identified during the sediment investigations at OU No. 2. If sediment contaminant concentrations are above the ER-M, adverse effects on the biota are considered probable. If contaminant concentrations are between the ER-M and ER-L, adverse effects on the biota are considered possible, and EPA recommends conducting toxicity tests as a follow-up. Finally, if contaminant concentrations are below the ER-L, adverse effects on the biota are considered unlikely (USEPA, 1992b).

The sediment quality summary/conclusions are discussed in the following sections.

Wallace Creek

Sediment concentrations of copper, lead, silver, zinc, 4,4'-DDE, 4,4'-DDD, 4,4'-DDT, dieldrin, PCB-1260, benzo(a)pyrene, fluoranthene, and pyrene exceeded the Region IV lower 10 percentile (ER-L) and/or median percentile (ER-M) sediment screening values (SQSV) in some of the samples. The exceedences of the TAL inorganics occurred in both upstream and downstream samples. Copper concentrations exceeded regional values at one station upstream of Sites 6 and 82. Lead concentrations were in exceedence in upstream, adjacent, and downstream stations. Zinc exceeded regional values at one station upstream and two downstream stations to Sites 6 and 82.

Dieldrin was detected in the uppermost station only. The remaining pesticides and PCBs exceeded the SQSV primarily in adjacent and downstream samples and their presence might be attributable to site runoff. The PAHs only were detected near roadways.

In addition, several TAL inorganics and TCL organics had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in Wallace Creek to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

Bear Head Creek

Sediment concentrations of lead, 4,4'-DDE, 4,4'-DDD, 4,4'-DDT, PCB-1260, and benzo(a)pyrene exceeded the ER-L and/or ER-M SQSVs in some of the samples. The exceedences of lead occurred in both upstream and downstream samples and, therefore, do not appear site related. The pesticides and PCBs exceeded the SQSV primarily in adjacent and

downstream samples and their presence might be attributable to site runoff. The PAHs exceeded the SQSV near the roadway only.

In addition, several TAL inorganics and TCL organics had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in Bear Head Creek to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

<u>Ravine</u>

Sediment concentrations of cadmium, lead, mercury, silver, zinc, 4,4'-DDE, 4,4'-DDD, 4,4'-DDT, dieldrin, endrin, PCB-1260, and several PAHs exceeded the ER-L and/or ER-M SQSVs in some of the samples. These constituents probably are attributable to site runoff.

Cadmium and silver concentrations in the sediments exceeded regional values at one ravine station in the northern section of Site 6. Lead values were in exceedence at one station in the southern section of Site 82. Mercury exceeded regional values at the two stations within Site 6 and one station in the northern section of Site 82. Zinc concentrations were in exceedence at one station in northern section of Site 6 and three stations throughout Site 82. The concentrations of 4', 4'-DDE; 4', 4'-DDD; and 4', 4'-DDT were in exceedence at one station in the northern section of Site 6 and throughout the ravine stations within Site 82. Dieldrin was in exceedence at one station within Site 6 and one station in the southern section of Site 82. Whereas, endrin was only found at one station within Site 6. PCBs were in exceedence in the two ravine stations in Site 6 and one station in the southern section of Site 82. PAHs were in exceedence of regional values at one station in the northern section of Site 6.

In addition, several TAL inorganics and TCL organics had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in the ravine to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

Surface Soil Quality

The surface soil quality summary/conclusions are discussed in the following sections. The following paragraphs discuss effects on terrestrial life from the metals for which toxicological information was found.

Site 9

None of the metals detected in the Site 9 surface soil for which toxicological information was available exceeded the applicable values.

Site 6 (Lot 201)

Surface soil concentrations of chromium detected at Site 6 (Lot 201) exceeded published toxicological values and potentially may cause adverse effects to terrestrial life.

Site 6 (Lot 203)

Surface soil concentrations of chromium, copper and zinc detected at Site 6 (Lot 203) exceeded published toxicological values and potentially may cause adverse effect to terrestrial life.

Sites 6 (Wooded and Ravine Areas) and 82

Surface soil concentrations of arsenic, copper, and zinc detected at Sites 6 (Wooded and Ravine Areas) and 82 exceeded published toxicological values and potentially may cause adverse effects to terrestrial life.

Fish

The fish summary/conclusions are discussed in the following sections.

Population Statistics

The summary/conclusions for the fish population statistics are discussed in the following sections.

Wallace Creek

The majority of the individuals collected at Wallace Creek were represented by juveniles representing the following species: eastern mosquito, shiner sp., pumpkinseed and the American eel.

Community similarity indices showed the greatest similarity between Stations 6-BH6A and 6-WC6A (0.53) and the least similarity between Stations 6-BH6A and 6-WC11 (0) and Stations 6-WC4 and 6-WC11 (0). Because a limited number of fish were collected at all the stations, the similarity values are not reliable.

The diversity of fishes collected at Wallace Creek varied within the stations. Typically, estuarine environments produce a high biomass and abundance, but are limited in the quantity of species. As with the similarity values, the diversity values are not representative of the creek due to the limited data set.

At Wallace Creek, there were no anomalies observed on the fish such as lesions, bacterial or viral infections.

The fish community at Wallace Creek appeared healthy and the population statistics did not indicate that the environment was impacted by contaminants of concern from OU No. 2.

Bear Head Creek

The majority of the individuals collected at Bear Head Creek were represented by juveniles which included, eastern mosquito, spot, and pumpkinseed.

Community similarity indices showed the greatest similarity between Stations 6-BH6A and 6-WC6A (0.53) and the least similarity between Stations 6-BH6A and 6-WC11 (0) and Stations 6-WC4 and 6-WC11 (0). Because a limited number of fishes were collected at all the stations, the similarity values are not reliable.

The diversity value derived from the fish collected at Bear Head Creek was 0.29. Typically, estuarine environments produce a high biomass and abundance, but are limited in the quantity of species. As with the similarity values, the diversity values are not representative of the creek due to the limited data set.

ES-15

At Bear Head Creek, there were no anomalies observed on the fish such as lesions, bacterial or viral infections.

The fish community at Bear Head Creek appeared healthy and the population statistics did not indicate that the environment was impacted by contaminants of concern from OU No. 2.

Pettiford Creek

The individuals collected at Pettiford Creek included, shiner sp., pumpkinseed, and striped mullet. Because of the limited numbers of fishes that were collected, conclusions regarding population were limited.

The only diversity value derived from the fish collected at Pettiford Creek was 0.45. Typically, estuarine environments produce a high biomass and abundance, but are limited in the quantity of species.

At Pettiford Creek, there were no anomalies observed on the fish such as lesions, bacterial or viral infections.

The fish community at Pettiford Creek appeared healthy and the population statistics did not indicate that the environment was impacted by contaminants.

Tissue Analysis

The summary/conclusions for the fish tissue analysis are discussed in the following sections.

Wallace Creek

Toluene, silver, benzene, and selenium were detected in fish and crab tissue samples. The fish tissue concentrations were within the range of tissue concentrations for these contaminants reported in ecological studies. Because of the frequency of detection of these contaminants both upstream and downstream from OU No. 2, the contaminants may not be attributed to the sites. Due to the limited database, additional studies are recommended to better assess whether contaminants present in fish are due to the migration of contaminants from the operable unit.

The fish community at OU No. 2 had elevated tissue concentrations of the following contaminants of concern: pesticides, PCBs, trichloroethene, and zinc. Due to the nature of the contaminants of concern, these constituents may be attributed to OU No. 2. The crab tissues had elevated levels of phenols, although the contaminant may not be attributed to the site.

Bear Head Creek

Toluene, cadmium, benzene and selenium were detected in fish and crab tissue samples. The fish tissue concentrations were within the range of tissue concentrations for these contaminants reported in ecological studies. Because of the frequency of detection of these contaminants both upstream and downstream from OU No. 2, the contaminants may not be attributed to the sites.

The fish community in Bear Head Creek had elevated tissue concentrations of the following contaminants of concern: pesticides, PCBs, and zinc. Due to the nature of the contaminants of concern, these constituents may be attributed to OU No. 2.

Pettiford Creek

Baker was not tasked with collecting fish for tissue analysis at Pettiford Creek.

Benthic Macroinvertebrate

The benthic macroinvertebrate summary/conclusions are discussed in the following sections.

Wallace Creek

Species richness in Wallace Creek was highest in the upstream stations (7-12 species) and lowest in the downstream stations (0-3 species). Species density followed a similar pattern with approximately 1,200 individuals/m² in the upper reaches and approximately 50 individuals/m² in the lower reaches of the creek. Species diversity was less than 0.5 at all the sampled stations on Wallace Creek.

The dominant species in the creek varied from the chiromid species <u>Tribelos jucundum</u> (74 percent of the individuals) in the upper reaches, the amphipod <u>Gammarus</u> <u>fasciatus</u> (64

percent of the individuals) in the mid-reaches, and the polychaetes <u>Nereis succinea</u> and <u>Capitella capitata</u> (five of the eight individual) and the oligochaete <u>Limnodrilus hoffmeisteri</u> (three of the eight individuals) in the lower reaches of Wallace Creek. This variation followed the variation in salinity measurements at the stations and indicated the effects of the tidal influence seen in the transition from a freshwater system in the upper reaches of the creek and the estuarine influence in the lower reaches of the creek.

The Macroinvertebrates Biotic Index (MBI) ranged from good-fair (6.46) in the upper reaches of the creek to poor (9.8) in the lower reaches of the creek. However, the salinity gradient influenced the species composition in the lower reaches with the tolerant freshwater oligochaete species being present. In addition, the presence of the salt wedge and low dissolved oxygen can create an adverse habitat for intolerant species.

Bear Head Creek

Species richness in Bear Head Creek was highest in the upstream stations (16-33 species) and lowest in the downstream station (one species). Species density followed a similar pattern with approximately 2,700 to 3,700 individuals/m² in the upper reaches and approximately 25 individuals/m² in the lower reaches of the creek. Species diversity was less than 1.0 at the upper reach station and less than 0.5 in the mid-reach station. Only one species was found in the lower reach station.

The dominant species in the creek varied from the oligochaete species <u>Isochaetides</u> <u>curvisetosus</u> (45 percent of the individuals) in the upper reaches, the bivalve <u>Pisidium</u> <u>casertanu</u> (70 percent of the individuals) in the mid-reaches, and the polychaete <u>Nereis</u> <u>succinea</u> (100 percent of the individuals) in the lower reaches of Bear Head Creek. This variation followed the variation in the salinity measurements at the stations and indicated the effects of the tidal influence seen in the transition from a freshwater system in the upper reaches of the creek and the estuarine influence in the lower reaches of the creek.

The MBI was poor and ranged from 7.51 in the upper reaches of the creek to 7.06 in the midreach of the creek. However, the salinity gradient influenced the species composition in the lower reach with no freshwater species being present. In addition, the presence of the salt wedge and low dissolved oxygen can create an adverse habitat for intolerant species.

Pettiford Creek

Four species were collected in Pettiford Creek and species density was 210 individuals/m². Species diversity was less than 0.5 at the sampled station on Pettiford Creek. The dominant species in the creek was the oligochaete <u>Limnodrilus hoffmeisteri</u> (70 percent of the individuals). The MBI was poor at 8.84.

Terrestrial Receptors

Total exposure to the COCs in the soil and surface waters by the terrestrial receptors was evaluated by estimating the chronic daily dose and comparing this dose to terrestrial reference values (TRVs). Indicator species used in this analysis were the whitetailed deer, cottontail rabbit and the quail. The exposure points for these receptors are the surface soils and surface water (surface soils from site 6, Lot 201; Site 6, Lot 203; Sites 6, Wooded areas and Ravine, Site 82; and Site 9; Surface water from Wallace Creek). The routes for terrestrial exposure to the COCs in the soil and water are incidental soil ingestion, drinking water ingestion, and vegetation ingestion. Estimates of the potential risk to the terrestrial receptors were made by comparing the total exposure of the COCs to the TRVs using the Quotient Index (QI) method. Ratios of less than unity indicate a low likelihood of adverse effects while a ratio above unity indicate the likelihood of an adverse affect to the receptor. For the COCs that had available TRVs, the QI did not exceed unity for any of the indicator terrestrial receptors.

Ecological Significance

The objective of the ERA was to determine if past reported disposal practices at OU No. 2 were adversely impacting the ecological integrity of the terrestrial environment or of Wallace Creek, Bear Head Creek, or the ravine. The ecological significance of the results is necessary to provide the risk managers with the requisite information, to be used in conjunction with the human health risk assessment, in order to determine the appropriate remedial action at the site for the protection of public health and the environment.

Based on the above findings, past reported disposal practices at OU No. 2 potentially are adversely impacting the ecological integrity of Wallace Creek, Bear Head Creek, or the ravine. The findings do not indicate a potentially adverse impact to vertebrate terrestrial receptors.

1.0 INTRODUCTION

This Ecological Risk Assessment (ERA) for Operable Unit No. 2 (Sites 6, 9 and 82), has been prepared in accordance with the scope of work identified under Task 6 in the Final Remedial Investigation/Feasibility Study Work Plan (May 1992), prepared by Baker Environmental, Inc. (Baker), under Contract Task Order (CTO) 0133. The ERA has been conducted in conjunction with a remedial investigation/feasibility study (RI/FS) at Operable Unit No. 2 (OU No. 2) under the Department of Navy's Comprehensive Long-Term Environmental Action - Navy (CLEAN) Program, Contract N62470-89-D-4814. The RI and FS documents have been submitted under a separate cover.

1.1 Objectives of the Ecological Risk Assessment

The objective of the ERA is to determine if past reported disposal practices at OU No. 2 are adversely impacting the ecological integrity of the terrestrial environment or of Wallace Creek, Bear Head Creek, or the ravine. This assessment also evaluated the potential effects of contaminants at OU No. 2 on sensitive environments including wetlands, protected species, and fish nursery areas. The conclusions of the ERA will be used in conjunction with the human health risk assessment in order to determine the appropriate remedial action at this site for the overall protection of public health and the environment.

1.2 Scope of the Ecological Risk Assessment

The ERA will evaluate and analyze the results from the remedial field investigation conducted as part of CTO 0133 and historical data collected during previous studies. The remedial field investigations include sampling and chemical analysis of the surface water, sediments, soil, and groundwater. In addition, ecological field investigations were conducted including collecting fishes for population statistics and chemical analysis of their tissues; collecting benthic macroinvertebrates for population statistics; and collecting blue crabs for chemical analysis of their tissues. Finally, information used to evaluate sensitive environments was obtained from historical data and previous studies conducted at Marine Corps Base (MCB) Camp Lejeune, North Carolina.

The risk assessment methodologies used in this evaluation are consistent with those outlined in the <u>U.S. EPA Supplemental Risk Assessment Guidance for the Superfund</u>, Volume II, Environmental Evaluation Manual (USEPA, 1989a). In addition, information found in the following documents were used to supplement the EPA guidance document:

- Framework for Ecological Risk Assessment (USEPA, 1992a)
- Ecological Assessment of Hazardous Waste Sites: A Field and Laboratory Reference (USEPA, 1989b)
- <u>Rapid Bioassessment Protocols for use in Streams and Rivers: Benthic</u> <u>Macroinvertebrates and Fish</u> (USEPA, 1989c)

2.0 SITE BACKGROUND

This section includes a discussion of the site setting, history, study area and a summary of the remedial investigation conducted at OU No. 2.

2.1 Site Description

There are three distinctive sites within OU No. 2. The following section describes the background of each site.

2.1.1 Site 9

Site 9 covers an area of approximately 2.6 acres. Site 9 is bounded by Holcomb Boulevard on the west, Site 6 to the north, Piney Green Road on the east and Sneads Ferry Road on the south. Locally, the site is bounded by unnamed streets leading to various storage buildings in the vicinity. Site 9 consists of an asphalt-lined fire training pit, an oil/water separator, five aboveground storage tanks (ASTs), and a fire tower (smoke house). The fire training pit, located in the southern area of the site, is used to conduct training exercises for extinguishing fires caused by flammable liquids. The oil/water separator is located next to the fire training pit to collect water used in the training exercises and storm water that falls into the pit. The recovered product collected in the oil/water separator is disposed of offsite. Two of the ASTs at Site 9 are 2,500-gallon steel tanks labeled "DO NOT USE". These tanks are not currently in use. Two additional storage tanks are located in a bermed area. These tanks are constructed of steel and contain approximately 500 gallons each. Two pressurized containment tanks are also located at Site 9. Their contents are unknown. The smoke house, located in the northern part of Site 9, is also used for training exercises. No fuel products are used in this area.

2.1.2 Site 6

Site 6 is located north of and adjacent to Site 9. Site 6 is bounded by Site 82 on the north , by Piney Green Road on the east, by Site 9 on the south, and by Holcomb Boulevard on the west. Site 6 covers an area of approximately 177 acres that incorporates Storage Lots 201 and 203, the wooded area behind the storage lots, and a ravine which begins at Site 6 and bisects Site 82. Three surface water bodies were associated with Site 6 for the purpose of this RI: Wallace Creek, Bear Head Creek, and a ravine (intermittent surface water body) located in the wooded area north of Lot 203 that drains to Wallace Creek. Specific details of the individual areas that make up Site 6 are described below.

2.1.2.1 Storage Lot 201

Storage Lot 201 (Lot 201) is a fenced lot located in the south-west portion of Site 6. It is a flat area with sparse vegetation around the fence lines. The ground surface is densely compacted soil. Lot 201 is bordered by woods and Bear Head Creek to the south, by Holcomb Boulevard to the west and Piney Green Road to the east. The lot is approximately 25 acres in size. It is currently being used for the storage of military vehicles and equipment, lumber, hydraulic oils and lubricants, non-PCB transformers, and other supplies (ESE, 1991).

2.1.2.2 Storage Lot 203

Storage Lot 203 (Lot 203) is a fenced lot located in the northern portion of Site 6. The fenced area of the lot encompasses approximately 46 acres. Lot 203 is a relatively flat area with elevation differences of approximately five feet. The ground surface is comprised of both naturally existing soil and fill material. Lot 203 varies in vegetation from a hard compact surface with no vegetation to areas with loose sandy soil and dense vegetation. Lot 203 is bordered by woods to the north (Site 82) and south, Piney Green Road to the east, and Holcomb Boulevard to the west. Lot 203 is currently inactive, but it still contains randomly stored scrap materials from former activities such as rubber rafts, shredded tires, radio/ communications parts, empty ammunition boxes, spent ammunition casings, fiberglass-like material, barbed wire fencing, used demolition kit training materials, a non-PCB transformer, wooden pallets, shredded tires, metal debris, and 55-gallon drums.

The 55-gallon drums found on Lot 203 were observed in small groupings throughout the lot. The majority of the drums, if labeled, were identified as containing lubricants, petroleum products, or corrosives. Drum sampling was conducted as part of the RI. The results of the drum sampling are provided in Section 4.0 of the Remedial Investigation report (Baker, 1992). The drums will be removed during the non-time critical removal action.

Empty storage tanks were also found on Lot 203. They were labeled as containing diesel fuel, gasoline, and kerosene (Baker, 1992). These tanks will also be removed during the non-time critical removal action.

2-2

2.1.2.3 Wooded and Ravine Areas

Woods and open fields surround both Storage Lots 201 and 203 and make up the remaining area of Site 6. The topography of the wooded areas is relatively flat, but localized trenching and mounding is visible west of Piney Green Road. The wooded areas are randomly littered with debris including spent ammunition casings, and empty or rusted drums. Many of the drums observed were only shells or fragments of drums. (Baker, 1992)

A ravine is located in the north west section of Site 6. The ravine begins "inside" of Storage Lot 203 and bisects Site 82. The elevation ranges from 25 feet above msl at the north boundary of Lot 203 to 5 feet above msl where the ravine drains into Wallace Creek. The surface of the ravine area is littered with various debris including batteries, fencing, tires, empty unlabeled drums, wire cables, commercial ovens, commodes, and respirator cartridges. An empty drum labeled "DDT" was also found in the ravine area, as were small canisters labeled to contain "DDT". The date on the canisters was marked November, 1957.

2.1.3 Site 82

Site 82 (more commonly referred to as "Piney Green Road VOC Site") is situated at the northern end of OU No. 2. It is bordered to the north by Wallace Creek, to the east by Piney Green Road, to the west by Holcomb Boulevard, and to the south by Site 6. Site 82 encompasses approximately 30 acres and is predominantly covered by woodlands. The site is randomly littered with debris including communication wire, spent ammunition casings, and empty or rusted drums. Markings were observed on a few drums, however, most of the drums did not contain markings due to their condition and age. Some of the drums were marked as "lubrication oil" and "anti-freeze".

The topography within Site 82 is relatively flat near the southern portion of the site, but becomes very steep near the bank of Wallace Creek. Localized trenching and mounding is visible near the southern portion of the site. The ravine bisects the site, as shown on Figure 3-1.

2.2 <u>Site History</u>

The following paragraphs describe the documented history of OU No. 2. Waste storage and disposal activities at the individual sites are described below.

2.2.1 Site 9

Site 9 has been used as a fire fighting training area from the early 1960s to the present. Fire extinguishing activities took place in an unlined pit. In 1981 the pit was lined with asphalt. The training fires in the pit were started with used oil, solvents, and contaminated fuels (unleaded). Approximately 30,000 to 40,000 gallons of JP-4 and JP-5 fuel were also burned in the fire training pit. Chemical retardants containing diethylene glycol monobutyl ether, proprietary mixtures of hydrocarbons, fluorosurfactants and inorganic salts were occasionally used to extinguish the training fires (Baker, 1992).

2.2.2 Site 6

Site 6 has a long history of various uses including the disposal and storage of wastes and supplies. This section on the history of Site 6 has been broken down into Storage Lot 201, Storage Lot 203, and the wooded and the ravine areas to simplify the historical descriptions of these areas.

2.2.2.1 Storage Lot 201

Currently, Lot 201 is used to store military equipment, vehicles, hydraulic oils, and other "non-hazardous" supplies. Pesticides were reportedly stored in the northeast and southeast corners of the lot. Transformers containing PCBs were reportedly stored in the southwest corner of the lot (Water and Air Research, 1983). No storage or disposal activities have supporting documentation other than what is reported in the Initial Assessment Study prepared in 1983 by Water and Air Research.

2.2.2.2 Storage Lot 203

Storage Lot 203 has been used as a disposal area since the 1940s. There is little documentation on the disposal activities at this lot. Lot 203 is not currently active as a storage or disposal area, but the ground surface is littered with various debris. Pesticides were

2-4

reported to have been stored in a trailer on Lot 203 as well as in the southeast portion of the lot (Memo: Past Disposal Practices at DRMO Lot 203, 17 January 1989). Drums of DDT were found in the southwestern portion of the lot in 1989 (Memo: Unearthed 55-gallon drums of DDT and 55-gallon drums of unknown substance at Camp Lejeune DRMO Lot 203. 18 January 1989). Five 55-gallon drums and surrounding soil were containerized and disposed of (Memo: 18 January 1989).

Lot 203 was also used for the storage and disposal of radio and communication parts, shredded tires, lubricants, petroleum products, corrosives, expended demolition kit training materials, ordnance, sheet metal debris, wire cables, and wooden pallets. Empty and full 55-gallon drums were found at various locations on Lot 203. A drum survey was conducted as part of the RI and the results are located in Section 4.0 of the Remedial Investigation report (Baker, 1992).

Lot 203 is currently fenced. From historical photographs, it appears that the fenced boundaries have changed since the lot was in operation. Former employees at Lot 203 have reported disposal of various chemicals including PCBs, cleaning solvents, electrolytes from used batteries, and waste oils.

2.2.2.3 Wooded and Ravine Areas

The surface of the wooded areas around Lots 201 and 203 is randomly littered with debris including drums, metal storage containers, and rocket cartridges. No organized disposal operations are documented for the wooded areas. A ravine begins at the northern boundary of Lot 203. As previously stated, this area is currently littered with various debris. From the deposition of the debris in the ravine, it appears that trucks may have dumped their contents into the ravine from Lot 203.

2.2.3 Site 82

As described in Section 2.1.3, Site 82 is randomly littered with debris. No organized disposal operations are documented for the site. From the deposition of the debris at Site 82, it appears that the area was used for disposal of miscellaneous debris from Lot 203. Although the name of the site refers to VOCs (the site is named "Piney Green Road VOC Area"), there are not documents or memorandums which indicate any disposal of VOCs or solvents.

2.3 <u>Study Area Description</u>

This section describes the overall study area at MCB Camp Lejeune, North Carolina. The information in this section was obtained from previous studies conducted at the base, or from the available literature.

2.3.1 Regional Ecology

MCB Camp Lejeune, North Carolina, is approximately 108,800 acres, with 84 percent of the area covered by forests (USMC, 1987). The base drains primarily to the New River or its tributaries including Northeast Creek, Southwest Creek, Wallace Creek, French Creek, Bear Head Creek, Freeman Creek, and Duck Creek. The soil types range from sandy loams to fine sand and muck, with the dominant series being sandy loam (USMC, 1987).

Vegetation at MCB Camp Lejeune, North Carolina, includes pure pine stands of loblolly and longleaf pine in the drier upland soils, pure pond pine stands in high organic wet soils, pinehardwood and pure hardwood stands in streamside zones and in more productive soils, and bottomland hardwoods in the floodplains of the major creeks (USMC, 1987). Wildlife on the base includes white-tailed deer, wild turkey, and black bear along with numerous small game species (e.g., bobwhite quail, morning dove, rabbit) (USMC, 1987).

Wallace Creek and Bear Head Creek are designated as Class SB NSW by the North Carolina Department of Environment, Health, and Natural Resources (NCDEHNR), which are saltwaters protected for primary recreation (swimming on a frequent basis), fishing, and aquatic life including propagation and survival (NCDEHNR, 1992a, 1992b). These creeks are classified as Nutrient Sensitive Waters which are waters subject to growths of microscopic or macroscopic vegetation requiring limitations on nutrient inputs (NCDEHNR, 1992a, 1992b). Wallace Creek is classified as Inland Waters above, and Coastal Waters below the first bridge upstream from its mouth (NCMFC, 1992). Wallace Creek and Bear Head Creek are classified as Inland Waters at all the sample stations.

The New River, downstream of OU No. 2, is designated as Class SC: which are saltwaters protected for secondary recreation, fishing, and aquatic life including propagation and survival (NCDEHNR, 1992a, 1992b). All saltwaters in North Carolina are classified to protect these uses at a minimum (NCDEHNR, 1992a, 1992b). This section of the New River also is classified as a Nutrient Sensitive Water (NCDEHNR, 1992a, 1992b).

2.3.2 Sensitive Environments

This section describes the sensitive environments that were evaluated at OU No. 2. These sensitive environments include wetlands, protected species, and other potentially sensitive environments.

2.3.2.1 Wetlands

The NCDEHNR's, Division of Environmental Management (DEM) has developed guidance pertaining to activities that may impact wetlands (NCDEHNR, 1992c). In addition, certain activities impacting wetlands also are regulated by the U.S. Corps of Engineers.

The U.S. Fish and Wildlife Service (FWS) prepared a National Wetlands Inventory (NWI) map for the Camp Lejeune, North Carolina quadrangle by stereoscopic analysis of high altitude aerial photographs (USDI, 1982). OU No. 2 is included in this map (see Appendix A for a copy of the NWI map). The wetlands were identified on the photographs based on vegetation, visible hydrology, and geography in accordance with <u>Classification of Wetland and Deep-Water Habitats of the United States</u> (Cowardin, et al, 1979). NWI maps are intended for a initial identification of wetland areas. They cannot be substituted for an actual wetland delineation that may be required by Federal, state and/or local regulatory agencies.

Several types of wetlands have been identified adjacent to Wallace Creek and Bear Head Creek from the NWI map. The wetlands along the creeks primarily are palustine forested wetlands consisting of pond, longleaf or loblolly pines, along with oaks, black gum and baldcypress (NCDNRCD, 1988). See the NWI map in Appendix A for the wetland classifications and their locations.

2.3.2.2 Threatened and Endangered Species

Certain species have been granted protection by the FWS under the Federal Endangered Species Act (16 U.S.C. 1531-1543), and/or the North Carolina Wildlife Resources Commission, under the North Carolina Endangered Species Act (G.S. 113-331 to 113-337). The protected species fall into one of the following status classifications: Federal or State endangered, threatened or candidate species, State special concern, State significantly rare, or State watch list. While only the Federal or State threatened or endangered and State special concern species are protected from certain actions, the other classified species have the potential for protection in the future.

Table 2-1 lists the protected faunal species (either endangered, threatened, or special concern) and the only federally endangered or threatened floral species that have been identified in previous studies within the boundaries of MCB Camp Lejeune (USMC, 1991; LeBlond, 1991; Fussell, 1991; and Walters, 1991). The following paragraphs discuss the protected species observed at MCB Camp Lejeune during previous studies.

A Peregrine falcon was spotted approximately five miles southeast of OU No. 2 (Fussell, 1991). These birds potentially may inhabit or feed in areas surrounding OU No. 2 because of their large foraging range. Black skimmers and piping plovers were observed near the New River Inlet (Fussell, 1991). However, these birds primarily inhabit shore line areas and, therefore, are not expected to be found at OU No. 2. Bachmans sparrows and Red-cockaded woodpeckers were observed at numerous locations throughout southern MCB Camp Lejeune. None of these species were observed at OU No. 2 during intensive investigations previously conducted for MCB Camp Lejeune, therefore, there is a low potential for them to exist at OU No. 2 (Fussell, 1991; Walters, 1991).

Sea turtles and sea turtle nests have been observed downstream of OU No. 2 in the New River on Onslow Beach. Sea turtles do not swim very far up the New River because of the low salinity, therefore, they are not expected to inhabit areas of OU No. 2 (USMC, 1991). During the ecological investigation conducted in August and September 1992, an alligator was observed in Wallace Creek. In addition, signs were posted at the boat launching ramp in Wallace Creek warning of the American alligators presence in the creek.

A protected floral species and special-interest community survey previously was conducted at Camp Lejeune (LeBlond, 1991). From this list, the Rough-leaf loosestrife was the only Federally threatened or endangered plant species found on the Marine Corp Base. Several State endangered or threatened and Federal and State candidate species were found on the MCB. A road meadow, inhabited by the state watch species <u>Lugwigia microcarpa</u>, was located upstream of OU No. 2 on Wallace Creek (see Appendix B).

Also upstream of OU No. 2 on Wallace Creek, a state registered natural resource area has been identified (see Appendix B). The general landscape consists of a broad floodplain and former mill pond on Wallace Creek which is dominated by a Cypress-Gum Swamp Community

TABLE 2-1

OPERABLE UNIT NO. 2 PROTECTED SPECIES WITHIN MCB CAMP LEJEUNE REMEDIAL INVESTIGATION CTO-0133 MCB CAMP LEJEUNE, NORTH CAROLINA

Species	Protected Classification
American alligator (<u>Alligator mississippienis</u>)	T(f), T(s)
Bachmans sparrow (<u>Aimophilia aestivalis</u>)	SC
Black skimmer (<u>Rhynochops niger</u>)	SC
Green (Atlantic) turtle (<u>Chelonia m</u> . <u>mydas</u>)	T(f), T(s)
Loggerhead turtle (<u>Caretta caretta</u>)	T(f), T(s)
Peregrine Falcon (*)	(*)
Piping plover (<u>Charadrius melodus</u>)	T(f), T(s)
Red-cockaded woodpecker (Picoides borealis)	E(f), E(s)
Rough-leaf loosestrife (Lysimachia asperulifolia)	E(f), E(s)

Legend: SC = State Special Concern

- E(f) = Federal Endangered
- E(s) = State Endangered
- T(f) = Federal Threatened
- T(s) = State Threatened
- * The observer did not differentiate between the American eastern peregrine falcon [E (f), E (s)] or the Artic peregrine falcon [T(f), T(s)].

which grades upstream into a Coastal Plain Small Stream Swamp Community. The Cypress-Gum Swamp Community is dominated by <u>Taxodium distichum</u>, <u>Nyssa biflora</u>, <u>Acer rubrum</u>, <u>Ulmus alata</u>, and <u>Fraxinus pennsylvanica</u>. The Plain Small Stream Swamp Community is dominated by <u>Taxodium distichum</u>, <u>Nyssa biflora</u>, <u>Fraxinus pennsylvanica</u>, <u>Ulmus</u> <u>americana</u>, <u>Acer rubrum</u>, and <u>Liquidambar styraciflua</u>.

2.3.2.3 Other Sensitive Environments

In addition to wetlands and protected species, the presence of other sensitive environments, including those listed in 40 CFR Part 300, were evaluated. These sensitive environments are evaluated when assessing potential hazardous waste sites using the Hazard Ranking System. These sensitive environments and their presence or absence at OU No. 2 are discussed below.

- Marine Sanctuary OU No. 2 is not located within a Marine Sanctuary (NCMFC, 1992).
- National Park OU No. 2 is not located within a National Park (NPS, 1991).
- Designated Federal Wilderness Area OU No. 2 is not located within a Designated Federal Wilderness Area (WS, 1989).
- Areas Identified under the Coastal Zone Management Act The North Carolina Coastal Area Management Act (CAMA) regulates various types of Areas of Environmental Concern including estuarine waters, coastal wetlands, public trust areas, and estuarine shoreline through the establishment of unified policies, criteria, standards, methods, and processes (CAMA, 1974). Bearhead Creek, the inland portion of Wallace Creek and any coastal wetlands associated with these waters are regulated under CAMA. The tidal portions of Wallace Creek along with 75 feet adjacent to the mean water line also are regulated under CAMA (NCDEHNP, 1993a).
- Sensitive Areas Identified under the National Estuary Program (NEP) or Near Coastal Waters Program (NCWP) - OU No. 2 is not located within a Sensitive Area identified under the NEP or NCWP (USEPA, 1993).
- Critical Areas Identified under the Clean Lakes Program OU No. 2 is not located within a Critical Area identified under the Clean Lakes Program (NPS, 1991).

- National Monument OU No. 2 is not located within a National Monument (NPS, 1991).
- National Seashore Recreational Area OU No. 2 is not located within a National Seashore Recreational Area (NPS, 1991).
- National Lakeshore Recreational Area OU No. 2 is not located within a National Lakeshore Recreational Area (NPS, 1991).
- National Preserve OU No. 2 is not located within a National Preserve (NPS, 1991).
- National or State Wildlife Refuge OU No. 2 is not located within a National or State Wildlife Refuge (NCWRC, 1992).
- Unit of the Coastal Barrier Resource Program OU No. 2 is not located within a unit of the Coastal Barrier Resource Program (USDI, 1993).
- Administratively Proposed Federal Wilderness Area OU No. 2 is not located within an Administratively Proposed Federal Wilderness Area (WS, 1989, 1993).
- Spawning Areas Critical for the maintenance of fish/shellfish species within river, lake, or coastal tidal waters. There are probable spawning areas for resident fish species within Wallace Creek and Bear Head Creek. However, specific areas have not been designated in these creeks by state agencies (NCDEHNR, 1993b).
- Migratory pathways and feeding areas critical for maintenance of anadromous fish species within river reaches or areas in lakes or coastal tidal waters in which fish spend extended periods of time OU No. 2 is not a migratory pathway or feeding area critical for the maintenance of anadromous fish species (NCDEHNR, 1993b). There is not a significant population of anadromous fish in Wallace, Bear Head Creek, or the New River downstream of Wallace Creek
- Terrestrial areas utilized for breeding by large or dense aggregations of animals A study of the terrestrial species was not conducted at OU No. 2. As discussed in the Regional Ecology section of this report several large terrestrial species inhabit MCB

Camp Lejeune. Therefore, there is the potential for breeding by large aggregations of animals. It should be noted that because of the frequent military activity on the land, and the fences around Lot 203 and Lot 201, the potential for breeding by terrestrial species on OU No. 2 may be limited.

- National river reach designated as Recreational Wallace Creek, Bear Head Creek, or the New River downstream of Wallace Creek are not designated as National Recreational Rivers (NPS, 1990, 1993).
- Federal designated Scenic or Wild River Wallace Creek, Bear Head Creek, or the New River downstream of Wallace Creek are not Federally designated Scenic or Wild Rivers (NPS, 1990, 1993).
- State land designated for wildlife or game management OU No. 2 is not located within a State game land (NCWRC, 1992).
- State designated Scenic or Wild River Wallace Creek, Bear Head Creek, or the New River downstream of Wallace Creek are not State designated Scenic or Wild Rivers (NCMFC, 1992).
- State designated Natural Area OU No. 2 is not located within a State designated Natural Area or Area of Significant Value (LeBlond, 1991).
- State designated areas for protection or maintenance of aquatic life No areas within the boundaries of OU No. 2 are designated as primary nursery areas or are unique or special waters of exceptional state or national recreational or ecological significance which require special protection to maintain existing uses (NCDEHNR, 1992b).
- Areas of Significant Value OU No. 2 is not located within a State Area of Significant Value (LeBlond, 1991).
- State Registered Natural Resource Area The Wallace Creek Natural Resource Area is located upstream of OU No.2.

2.4 <u>Remedial Investigations</u>

The RI involved four environmental areas; Soil Investigation, Groundwater Investigation, Surface Water/Sediment Investigation, and Ecological Investigation. A summary of the results of the soil and groundwater investigations conducted at OU No. 2 is presented in this section of the report; detailed descriptions of these studies as well as the complete results can be found in the RI Report for OU No. 2 (Baker, 1993). The surface water and sediment investigations are discussed in Section 3.0 (Surface Water/Sediment Sampling) of this report while the ecological investigation is discussed in Section 4.0 (Ecological Investigation) of this report.

2.4.1 Source Identification

The remedial investigations concluded that organic and inorganic contamination was present in soil, groundwater, surface water, and sediments at OU No. 2. The data collected suggest that multiple sources have contributed to contaminating all the media. The following discussion identifies potential sources of contamination with each site.

2.4.1.1 Potential Sources of Contamination at Sites 6 and 82

Within Sites 6 and 82, numerous sources of contamination may exist including surficial and buried drums, miscellaneous size containers, surface spills, and routine spraying activities (pesticides).

Drums and other miscellaneous size containers were observed throughout Sites 6 and 82 including south of Bear Head Creek, north and east of Lot 201, within Lot 203, the ravine, and wooded areas north of Lot 203 (Site 82). Some of the drums were labeled as lubricating oils, pesticides (ravine area), or paint solvents. It was also reported (Memo: 12 January 1989) that drums may have been buried within Lot 203 although test pit excavations revealed only a limited number of small (5-gallon) canisters. Containers of paints, lubricating oils, and various solvents were observed in test pits trenched outside of Lot 203 (wooded area between Lots 201 and 203). Unidentified pits such as these may exist throughout the wooded areas. Surface spills of hazardous materials were not reported at Site 6 but some these materials are known to have existed on site (e.g., Lot 203).

Most of the groundwater contamination identified in the southeast portion of Site 82 appears to be centered in the vicinity of one well. The source of this contamination may be related to buried drums or containers in the area. Numerous apparently empty containers were identified on the surface in this area. Additional investigative activities may be needed to further evaluate this area.

The ravine is a potential source of contamination at Site 6. The ravine is filled with debris such as drums and five-gallon containers of unknown material, weathered battery packs, spent shell casings, and miscellaneous refuse (mainly demolition debris). It is unknown what materials, if any, underlie this surface debris. Trenching may be required in the ravine to further evaluate this potential source.

Several other contaminated areas within Site 6 were identified including Lot 201 and the wooded areas north and east of Lot 201. Within Lot 201, the sources of contamination appear to be related to current (i.e., storage of vehicles and pesticide spraying) and former site activities (PCBs and pesticide storage areas). Pesticides are very prevalent in surface soil at Lot 201.

2.4.1.2 Potential Sources of Contamination at Site 9

Investigation results indicate that the environmental contamination at Site 9 is minimal. The potential sources of contamination, although minimal, include the aboveground storage tanks and fire-fighting training pit (Volatile Organic Compounds (VOCs) and Semivolatile Organic Compounds (SVOCs), and spraying of pesticides on the surface). Overall, the site poses little risk to human health.

2.4.2 Overview of Results and Extent of Contamination

TCL organic and TAL inorganic contamination identified at OU No. 2 appears to have resulted from past disposal practices and recent site activities. The data suggest that these occurrences have impacted soil, groundwater, sediment, and surface water at OU No. 2. Contaminant distribution patterns at Site 82 for all of the media suggest that there is a significant source of groundwater contamination which appears to be located in the wooded area north of Lot 203. The nature and extent of this source, however, have not been fully evaluated. Moreover, many other sources of contamination also exist (e.g., the ravine Site 6), which have contributed to the overall environmental contamination.

2-14

Migration of contaminants, especially TCL organics, have resulted in widespread environmental contamination at the northern end of Site 6 and in Site 82. The data suggest that the primary contaminant plume (e.g., solvents, lubricating oils, etc.) is migrating away from the wooded area north of Lot 203 and toward Wallace Creek. TCL organics are contaminating the surface water and sediments of Wallace Creek. Migration of contaminants from the ravine area also appears to be contaminating Wallace Creek. Moreover, TAL inorganic contamination (potential source appears to be numerous battery packs) appears to be migrating from the ravine to Wallace Creek.

Other source areas within Sites 6 and 82 have been identified. The contaminant magnitude at these other areas is not as significant, however, as the primary occurrence at Site 82. These impacted areas appear to be isolated and not widespread. The sources of the contamination within these areas may be the result of small disposal pits or spills from drums.

2.4.3 Soil Investigation

The surface soil samples were analyzed for Target Compound List (TCL) organics, and Target Analyte List (TAL) inorganics. A summary of the results of the soil investigation conducted at OU No.2 are included in this section.

2.4.3.1 Site 9

Surface soil (i.e., ground surface to 6-inches) analytical results indicated the presence of TCL organics (including pesticides, volatiles, and semivolatiles), TAL inorganics (excluding cyanide), and total petroleum hydrocarbons (TPH). The following paragraphs summarize the results of the sampling.

Pesticides 4,4'-dichlorodiphenyl dichloroethylene (4,4'-DDE) and 4,4'-dichlorodiphenyltrichloroethane (4,4'-DDT) were detected at five soil boring locations. Four Volatile Organic Compounds (VOCs) including acetone, 1,1,1-Trichloroethane (TCA), Tetrachloroethene (PCE), and toluene were detected in the soil collected from two soil borings.

Three Semi-Volatile Organic Compounds (SVOCs) including pyrene, bis(2-ethylhexyl) phthalate, and benzo(b)fluoranthene were detected in soil samples collected from two soil

borings. The concentration ranges of the positively detected TCL organic compounds are as follows:

	Concentration
<u>Constituent</u>	Range (ug/kg)
4,4'-DDE	13 to 650
4,4'-DDT	3.3J to 570
Acetone	16
1,1,1-TCA	1J
PCE	21
Toluene	2J
Pyrene	59J
Bis(2-ethylhexyl)	71J
phthalate	
Benzo(b)fluoranthene	46J

J - Represents that the value is estimated either for a tentatively identified compound or when a compound is present but the value is below the contract required quantitation limit.

1.5

Fifteen of the 23 TAL inorganics were detected in the surface soils. Antimony, arsenic, beryllium, cadmium, nickel, selenium, silver, and thallium were not detected in any of the surface soil samples. The concentration ranges of the positively detected TAL inorganics are as follows:

	Concentration
Constituent	Range (mg/kg)
Aluminum	1,510 to 4,510
Barium	4.9JB to 8.9B
Calcium	179B to 47,100
Chromium	1.7B to 5.1
Cobalt	0.5JB to 0.85JB
Copper	0.93JB to 2.8JB
Iron	813 to 1,260
Lead	4.1 to 25.7
Magnesium	64B to 811B

Manganese	4.1 to 14.7
Mercury	0.02B to 0.03B
Potassium	20.6JB to 152B
Sodium	106JB
Vanadium	2.7JB to 4.8B
Zinc	6.8 to 18.1

B - Represents that the value is above the instrument detection limit but is below the contract required quantitation limit.

2.4.3.2 <u>Site 6 (Lot 201)</u>

TCL organic and TAL inorganic chemicals were detected in the surface soil samples collected from Lot 201. Of the organics detected at the site, six were pesticides, two were PCBs, three were VOCs and twelve were SVOCs. The concentration ranges of the positively detected TCL organics are as follows:

	Concentration
Constituent	Range (ug/kg)
Dieldrin	5.6J to 4.6
4,4'-DDE	4J to 17,000J
4,4'-DDD	0.98J to 180,000J
4,4'-DDT	3 J to 1,200,000
Alpha chlordane	8.9
Gamma chlordane	8J
PCB-1248	1,800
PCB-1260	31J to 36J
Methylene chloride	4J
Acetone	7J to 37J
1,1,1-TCA	2J to 42
1,4-Dichlorobenzene	37J to 38J
Phenanthrene	36J
Di-n-butyl phthalate	89J
Fluoranthene	43J to 94J
Pyrene	38J to 99J
Benzo(a)anthracene	47J

Chrysene	39J to 88J
Bis(2-ethylhexyl)phthalate	68J to 310J
Di-n-octyl phthalate	44J
Benzo(b)fluoranthene	61J to 160J
Benzo(k)fluoranthene	46J
Benzo(a)pyrene	78J

il

Nineteen of the 23 TAL inorganics were detected in the surface soils. Antimony, mercury, silver, and thallium were not detected in any of the surface soil samples. The concentration ranges of the positively detected TAL inorganics are as follows:

	Concentration
Constituent	Range (mg/kg)
Aluminum	245 to 5,520
Arsenic	0.91B to 9.7J
Barium	3.5JB to 16.5B
Beryllium	0.22B
Cadmium	0.51JB to 1.5J
Calcium	402B to 286,000
Chromium	3.5 to 21.6
Cobalt	1.3JB
Copper	0.75JB to 27.8
Iron	238 to 4,260
Lead	1J to 78
Magnesium	26B to 3,980
Manganese	4.2J to 204J
Nickel	3.7B to 6.4JB
Potassium	30.6JB to 567B
Selenium	2.2J
Sodium	41.6JB to 312JB
Vanadium	1.6B to 18.3
Zinc	4.6 to 135J

2.4.3.3 Site 6 (Lot 203)

TCL organic and TAL inorganic chemicals were detected in the surface soil samples collected at Lot 203. The TCL organics detected at the site included eight pesticides, three PCBs, three VOCs, and 23 SVOCs. The concentration ranges of the positively detected TCL organics are as follows:

	Concentration
<u>Constituent</u>	Range (ug/kg)
Dieldrin	3.6J to 270J
4,4'-DDE	3.8J to 2,100
Endrin	21 to 130J
Endosulfan II	4.4J
4,4'-DDD	4.5J to 180J
4,4'-DDT	3.4J to 1,500J
Alpha chlordane	2.3J to 72J
Gamma chlordane	160J
PCB-1248	580J
PCB-1254	2100J
PCB-1260	17J to 42,000J
Acetone	4J to 15
1,1,1-TCA	2J to 15
Toluene	7J
1,4-Dichlorobenzene	34J to 160J
1,2-Dichlorobenzene	160J
Napthalene	1,400J
2-Methylnaphthalene	3,100J
Acenaphthene	250J to 9,500J
Dibenzofuran	140J to 890J
Fluorene	220J to 940J
Pentachlorophenol	520
Phenanthrene	60J to 2,000
Anthracene	55J to 440J
Fluoranthene	39J to 2,300
Carbazole	390J to 910J
Pyrene	42J to 2,800
Butyl benzyl phthalate	83J

3,3-Dichlorobenzidine	540
Benzo(a)anthracene	47J to 1,600
Chrysene	50J to 1,300
Bis(2-ethylhexyl)phthalate	52J to 1,300
Benzo(b)fluoranthene	88J to 2,700
Benzo(k) fluoranthene	30J to 1,100
Benzo(a)pyrene	49J to 1,800
Indeno(1,2,3-cd)pyrene	42J to 1,000
Benzo(g,h,i)perylene	41J to 1,000J

- ti

Twenty of the 23 TAL inorganics were detected in the surface soils at Lot 203. Selenium, silver, and thallium were not detected in any of the surface soil samples. The concentration ranges of the positively detected TAL inorganics are as follows:

	Concentration
Constituent	<u>Range (mg/kg)</u>
Aluminum	495 to 4,170
Antimony	13.5J to 51.2
Arsenic	0.39B to 4.9
Barium	2.7 JB to 47.8
Beryllium	0.21B
Cadmium	0.48JB to 9.3
Calcium	44.4B to 92,100
Chromium	1.1B to 25.2
Cobalt	0.39JB to 2.2B
Copper	1JB to 75
Iron	241 to 12,900
Lead	4.1 to 4,010J
Magnesium	12B to 1,680
Manganese	1.9 JB to 182
Mercury	0.03B to 1.1
Nickel	1.8JB to 13.2
Potassium	27.7 JB to 195 B
Sodium	9.2B to 460JB
Vanadium	1.1B to 8.2JB
Zinc	1.1B to 604

2.4.3.4 Sites 6 (Wooded and Ravine Areas) and 82

TCL organics and TAL inorganics were detected in the surface soil samples collected at Sites 6 and 82. Samples collected from the ravine are also discussed in Section 3.4 (Sediment Investigation).

TCL organics detected at the site included six pesticides and one PCB. Eleven VOCs including methylene chloride, bromomethane, acetone, 1,2-dichloroethene, PCE, 1,1,1-TCA, trichloroethene (TCE), benzene, 1,1,2,2-tetrachloroethene, toluene, and styrene were detected at Site 6 in the surface soil samples. Twenty-five SVOCs were also detected in the soil samples. The concentration ranges of the positively detected TCL organics are as follows:

	Concentration
Constituent	Range (ug/kg)
Dieldrin	4.6 to 87J
4,4'-DDE	2.2J to 4,200
Endrin	5.6J to 2,40J
4,4'-DDD	10J to 12,000
4,4'-DDT	3.4J to 400
Alpha chlordane	3.6J
PCB-1260	28J to 26,000J
Chloromethane	620J to 9,800
Bromomethane	670J to 3,700J
Acetone	5J to 14J
1,2-Dichloroethane	1,500J
1,1,1-TCA	1J to 2J
TCE	4,600
Benzene	850J
PCE	2,600J to 7,000J
1,1,2,2-Tetrachloroethene	55,000
Toluene	120J
Styrene	2J
Phenol	37J to 160J
1,4-Dichlorobenzene	39J to 74J
4-Methylphenol	120 J

Napthalene	71J to 140J
2-Methylnaphthalene	42J
Acenaphthylene	84J
Acenaphthene	36J to 370
Dibenzofuran	82J to 120J
Fluorene	130J to 200J
Phenanthrene	46J to 1,500
Anthracene	41J to 260J
Fluoranthene	40J to 2,000J
Carbazole	73J to 190J
Pyrene	72J to 2,700
Butyl benzyl phthalate	140J
Benzo(a)anthracene	39J to 2,200
Chrysene	44J to 1,600
Bis(2-ethylhexyl)phthalate	35J to 320J
Di-n-octyl phthalate	40J
Benzo(b)fluoranthene	54J to 2,200
Benzo(k)fluoranthene	25J to 490
Benzo(a)pyrene	40J to 1,500
Indeno(1,2,3-cd)pyrene	45J to 1,300
Dibenz(a,h)anthracene	43J to 380J
Benzo(g,h,i)perylene	40J to 1,300J

All 23 of the TAL inorganics were found at the sites. The concentration ranges of the positively detected TAL inorganics are as follows:

	Concentration
<u>Constituent</u>	Range (mg/kg)
Aluminum	177J to 19,200J
Antimony	3.5JB to 13.2JB
Arsenic	0.49B to 26.3
Barium	1.1JB to 1,410
Beryllium	0.06B to 2.2
Cadmium	0.4JB to 51.9
Calcium	59.6B to 174,000J
Chromium	0.72B to 54.6

2-22

Cobalt	0.34B to 13.7
Copper	0.39JB to 348
Iron	113 to 149,000
Lead	2 to 1710
Magnesium	12.3B to 2,580J
Manganese	1.1JB to 700
Mercury	0.02B to 3.9
Nickel	1.7B to 79.4
Potassium	15JB to 2,560
Selenium	0.9 to 5.8
Silver	0.47JB to 0.49JB
Sodium	9.6JB to 809JB
Thallium	0.35B to 0.57JB
Vanadium	0.36JB to 35.7
Zinc	1.6B to 16,600

2.4.4 Groundwater Investigation

Organic and inorganic contamination identified at OU No. 2 appears to have resulted from past disposal practices and recent site activities. The data suggest that these occurrences have impacted soil, groundwater, sediment, and surface water, in particular at Sites 6 and 82. Contaminant distribution patterns at Sites 6 and 82 for all of the media suggest that there is a significant source of contamination (i.e., TCL organic) present which appears to be located in the wooded area north of Lot 203. The nature and extent of this source, however, have not been fully evaluated. Moreover, many other sources of contamination also exist (e.g., the ravine, Site 6) which have contributed to the overall environmental impact.

Migration of contaminants, especially TCL organics, has resulted in wide spread environmental impact at Site 82. The data suggest that a primary contaminant plume (i.e., chlorinated hydrocarbons) is migrating away from the wooded area north of Lot 203 toward Wallace Creek. TCL organic contaminants are impacting the surface water and sediments of Wallace Creek. Migration of contaminants from the ravine (Site 6) area also appears to be impacting Wallace Creek. Moreover, TAL inorganic contamination (the potential source appears to be numerous battery packs) also appears to be migrating from the ravine. Other source areas within Site 6 have been identified. The contaminant magnitude at these other areas of concern is not as significant, however, as the primary occurrence at Site 82. These impacted areas appear to be isolated and not widespread. The sources of the contamination within these areas may be the result of small disposal pits or spills from drums.

3.0 SURFACE WATER/SEDIMENT INVESTIGATION

This section discusses the surface water and sediment investigations conducted at OU No. 2. Included in this section are the sampling methodologies, procedures, locations, and results of the surface water and sediment sampling.

3.1 Surface Water and Sediment Sampling Methodology

Surface water and sediment sampling was conducted to determine if contamination attributable to OU No. 2 exists in Wallace Creek, Bear Head Creek, or the ravine which had an intermittent tributary to Wallace Creek. Surface water samples were collected at twentyfour stations at OU No. 2, while sediment samples were collected at twenty-six stations (see Figure 3-1). The majority of the samples were collected from August 22 to August 30, 1992, with one sample collected on October 23, 1992 due to site access problems.

The following information from each station was recorded in the field logbook:

- Project location, date and time
- Weather
- Sample location number and identification number
- Flow conditions (i.e., high, low, in flood, etc.)
- On-site water quality measurements
- Visual description of water (i.e., clear, cloudy, muddy, etc.)
- Description of biotic community (i.e., flora, fauna, etc.)
- Sketch of sampling location including boundaries of the water body, sample location (and depth), relative position with respect to the site, location of wood identifier stake
- Names of sampling personnel
- Sampling technique, procedure, and equipment used

The on-site water quality measurements consisted of temperature, pH, specific conductance, salinity, and dissolved oxygen. These measurements were collected immediately following sample collection.

3.1.1 Surface Water

The following sections describe the stations where surface water samples were collected and the procedures used for collecting the samples.

3.1.1.1 Station Locations

Forty-eight surface water samples were collected from twenty-four stations at OU No. 2 (see Figure 3-1 for station locations). Twenty-eight samples (eleven stations) were collected from Wallace Creek, fourteen samples (seven stations) were collected from Bear Head Creek, and six samples (six stations) were collected from the ravine (two other ravine sampling stations were dry at the time samples were collected). Tables 3-1, 3-2 and 3-3 contain a summary of the station numbers and locations, and sample numbers for the surface water samples collected at those stations.

The surface water sample numbers were designated as 6-WC"X"-SW-06B; the 6 indicates that the samples were collected at OU No. 2, WC stands for Wallace Creek (BH stands for Bear Head Creek and RV stands for the ravine), "X" stands for the station number, SW stands for surface water, 06 stands for a sample collected at the surface (312 stands for a sample collected at the surface water/sediment interface), and B stands for a sample collected at the creek bank (M stands for a sample collected in the middle of the creek).

3.1.1.2 Sampling Procedures

At stations where the water was more than three feet deep, samples were collected at the surface by dipping the sample bottles directly into the water and at one foot above the sediment by using a kemmerer sampler. To determine the designated depth, a marked weighted line was lowered into the water with the depth to the sediments recorded. At stations where the water was less than three feet deep, samples were collected at the approximate vertical mid-point by dipping the sample bottles directly into the water.

Care was taken when collecting samples for analysis of VOCs to avoid excessive agitation that could result in loss of VOCs. Samples for the VOC analysis were collected prior to the collection of the samples for analysis of the other parameters.

The samples were collected in clean containers provided by the analytical laboratory. Sampling personnel wore clean PVC gloves at each sampling station. For those sample bottles already containing preservative (e.g., sulfuric acid), the water was collected in a clean container and then slowly poured into the sample bottle. All sample containers not containing preservative were rinsed at least once with the sample water prior to sample collection.

The downstream water samples were collected first, with subsequent samples taken while moving upstream. Any sediment or biological samples were collected after the water samples were taken to minimize sediment resuspension that might contaminate the water samples.

The sampling locations were marked by placing a wooden stake and bright colored flagging at the nearest bank or shore. The sample number was marked on the stake with indelible ink. Photographs were taken to document the physical and biological characteristics of the sampling location.

3.1.2 Sediment

The following sections describe the stations where sediment samples were collected and the procedures used for collecting the samples.

3.1.2.1 Station Locations

Sixty-three sediment samples were collected from twenty-six stations at OU No. 2 (see Figure 3-1 for station locations); thirty-two samples (eleven stations) were located in Wallace Creek, twenty samples (seven stations) were located in Bear Head Creek, and eleven samples (eight stations) were located in the ravine. Tables 3-1, 3-2 and 3-3 contain a summary of the station numbers and locations, and sample numbers for the sediment samples collected at those stations.

The sediment sample numbers were designated as 6-WC"X"-SD-06B; the 6 indicates that the samples were collected at OU No. 2, WC stands for Wallace Creek (BH stands for Bear Head Creek and RV stands for the ravine), "X" stands for the station number, SD stands for sediment, 06 stands for a sample collected from the top six inches of the sediment (612 stands for a sample collected from six to twelve inches of the sediment), and B stands for a sample collected at the creek bank (M stands for a sample collected in the middle of the creek).

3-3

3.1.2.2 Sampling Procedures

At each station, sediment samples were collected at the surface (0-6 inches) and at depth (6-12 inches) using a stainless steel hand-held coring instrument. A new disposable clear plastic liner tube, fitted with a disposable eggshell catcher to prevent sample loss, was used at each station.

The coring device was pushed into the sediments to a maximum depth of fifteen to twenty inches, or until refusal. The liner was removed from the sampler and the sediments were extruded into the appropriate sample jars using a decontaminated extruder. The liners were not cut in half as stated in the work plan because the plastic shavings may have contaminated the sediments.

3.2 Surface Water and Sediment Sampling Results

Surface water and sediment samples were collected from three areas at OU No. 2: Wallace Creek north of Site 82, Bear Head Creek south of site Site 6, and the ravine located on the northern portion of Site 6 (see Figure 3-1). Water quality measurements were conducted at each station using field instruments. Appendix C contains the field data sheets for the surface water and sediment samples.

3.2.1 Field Measurements

During the collection of the surface water and sediment samples, water quality measurements (i.e., salinity, conductivity, dissolved oxygen, and pH) were conducted using field instruments. Table 3-4 summarizes these measurements.

A salt wedge was observed at Stations 6-WC07, 6-WC08, 6-WC09, 6-WC10, 6-WC11, and 6-BH07 with the salinity of the overlying water (freshwater) ranging from 0.0 to 4.0 parts per thousand (ppt), and the salinity of the bottom water (saltwater) ranging from 6.0 to 8.5 ppt. The dissolved oxygen followed a similar trend at these stations ranging from 2.2 mg/l to 5.8 mg/l at the surface and 0.15 mg/l and 0.3 mg/l at the bottom of the salt wedge. Conductivity at these stations ranged from 300 to 7,000 microhms/cm at the surface and 500 to 14,000 microhms/cm at the bottom, and the pH ranged from 6.0 to 6.8 standard units (S.U.).

Salinity concentrations at the other stations was non-detectable, and conductivity concentrations ranged from 30 to 420 microhms/cm. Dissolved oxygen concentrations at the other stations ranged from 4.6 to 7.7 mg/l and pH values ranged from 3.9 to 6.8 S.U.

3.2.2 Surface Water

Surface water samples were collected at OU No. 2 in Wallace Creek, Bear Head Creek, and the ravine (see Figure 3-1). This sampling was performed to determine the extent of contamination in the surface water due to past disposal activities at OU No. 2. The extent of contamination is discussed in Section 3.3 of this report. In addition, potential source areas are discussed in Section 2.2 of this report. The surface water sampling activities are described in Section 3.1.1.

At some of the mid-creek stations, samples were not collected due to depth of water and restricted boat access. The bank samples from these stations were collected from shore, however, the middle stations samples could not be reached. Tables 3-1, 3-2 and 3-3 explain why samples were not collected at some of the stations.

3.2.2.1 Wallace Creek

TCL organic and TAL inorganic chemicals were detected in several surface water samples collected from Wallace Creek (see Tables 3-5 and 3-6). The data and frequency tables are provided in Appendix D. Of the TCL organics that were detected in Wallace Creek, six were VOCs (vinyl chloride, acetone, 1,2,-dichloroethene, TCE, PCE, and toluene) and two were SVOCs (2,4,6,-trichlorophenol and bis(2-ethylhexyl)phthalate). Pesticides and PCBs were not detected in any of the samples. The concentration ranges of the positively detected TCL organics and the sample number with the maximum are as follows:

	Sample	Concentration
Constituent	Number	Range (ug/l)
Acetone	WC09-SW-312M	4J to 900J
1,2,-dichloroethene	WC07-SW-06B	2.0J to 85
PCE	WC07-SW-06M	1.0J to 4.0J
TCE	WC07-SW-06M	3J to 98
Toluene	WC07-SW-06B	1J to 3J
Vinyl chloride	WC07-SW-06B	6.0J
2,4,6-Trichlorophenol	WC10-SW-06M	1J

WC11-SW-312M

1J to 2J

Bis(2-ethylhexyl) phthalate

Nineteen of the 24 TAL inorganics were detected in the samples. Antimony, beryllium, cyanide, selenium, and thallium were not detected in any of the samples. The positively detected TAL inorganics, and the sample number with the maximum detection are as follows:

	Sample	Concentration
Constituent	Number	<u>Range (ug/l)</u>
Aluminum	WC01-SW-06B	480J to 1,350
Arsenic	WC09-SW-06B	3.7B
Barium	WC05-SW-06M	16JB to 22.6B
Cadmium	WC-07-SW-312M	3.2JB to 17.4J
Calcium	WC11-SW-312M	3,640B to 64,100
Chromium	WC05-SW-312M	4.9B
Cobalt	WC05-SW-312M	2.9B
Copper	WC11-SW-312M	3B to 209
Iron	WC01 -SW-06B	477 to 1,050
Lead	WC03-SW-312M	1.2B to 10.4
Magnesium	WC11-SW-312M	632B to 174,000
Manganese	WC11-SW-312M	8.2JB to 25J
Mercury	WC11-SW-312M	0.24B to 0.52
Nickel	WC03-SW-312M	102 to 1,380
Potassium	WC11-SW-312M	341B to 1,620,000
Silver	WC08-SW-312M	2.6B
Vanadium	WC01-SW-06B	1.9JB to 3.3JB
Zinc	WC03-SW-312M	7.3B to 111

3.2.2.2 Bear Head Creek

TCL organics and TAL inorganics were detected in several surface water samples collected from Bear Head Creek (Tables 3-7 and 3-8). The data and frequency tables are provided in Appendix D. Two SVOCs (diethyl phthalate and bis (2-ethylhexyl) phthalate were positively detected in these samples. No VOCs, pesticides, or PCBs were detected in any of the samples. The concentration ranges and the sample number with the maximum detection are as follows:

	Sample	Concentration
<u>Constituent</u>	Number	Range (ug/l)
Diethyl phthalate	BH07-SW-312M	2J
Bis(2-ethylhexyl)	BH05-SW-06B	1J to 2J
phthalate		

Sixteen of the 24 TAL inorganics were detected in the samples. Antimony, arsenic, beryllium, cadmium, cobalt, cyanide, selenium, and thallium were not detected in any of the samples. The concentration ranges of the positively detected TAL inorganic compounds, and the sample number with the maximum detection are as follows:

	Sample	Concentration
Constituent	Number	<u>Range (ug/l)</u>
Aluminum	BH05-SW-06M	334 to 2,700
Barium	BH05-SW-06M	13.4B to 36B
Calcium	BH07-SW-312M	600B to 54,900
Chromium	BH05-SW-06M	4.4B to 8.0B
Copper	BH07-SW-312M	4B to 55.8
Iron	BH05-SW-06M	501 to 6,200
Lead	BH05-SW-06M	1.5JB to 8.2
Magnesium	BH07-SW-312M	588B to 13,600
Manganese	BH05-SW-06M	6.2B to 65
Mercury	BH07-SW-312M	0.05B to 0.34
Nickel	BH07-SW-312M	8.0JB to 244
Potassium	BH07-SW-312M	685B to 49,000
Silver	BH07-SW-06B	2.1B to 3.6B
Sodium	BH07-SW-312M	4,310JB to 1,260,000
Vanadium	BH03-SW-06M	2JB to 3JB
Zinc	BH07-SW-312M	6.2B to 30.7

3.2.2.3 <u>Ravine</u>

TCL organics and TAL inorganics were detected in several surface water samples from the ravine (Tables 3-9 and 3-10). The data and frequency tables are provided in Appendix D. Acetone (140 ug/l in sample RV5-SW-06) was the only TCL organic compound that was positively detected in these samples.

Seventeen of the 24 TAL inorganics were detected in the samples. Antimony, beryllium, cyanide, nickel, mercury, selenium, and thallium were not detected in any of the samples. The concentration ranges of the positively detected TAL inorganics, and the sample number with the maximum detection are as follows:

	Sample	Concentration
Constituent	Number	<u>Range (ug/l)</u>
Aluminum	RV2-SW-06	119B to 613
Arsenic	RV8-SW-06	2.2B to 10.5
Barium	RV2-SW-06	37.1JB to 91B
Cadmium	RV5-SW-06	3.7JB to 4.3JB
Calcium	RV2-SW-06	12,300 to 102,000
Chromium	RV7-SW-06	4.2B to 6.5B
Cobalt	RV8-SW-06	2.3B
Copper	RV5-SW- 06	4.7B to 9JB
Iron	RV8-SW-06	127J to 9,600
Lead	RV8-SW-06	1.9B to 12.2
Magnesium	RV2-SW-06	1,200B to 7,100
Manganese	RV5-SW-06	38.6J to 597
Potassium	RV2-SW-06	393B to 2,910B
Silver	RV6-SW-06	2.9B to 67.6
Sodium	RV8-SW-06	2,860JB to 8,960
Vanadium	RV8-SW-06	6.2B
Zinc	RV6-SW-06	72.7 to 495

3.2.3 Sediments

Sediment samples were collected at OU No. 2 in Wallace Creek, Bear Head Creek, and the Ravine (see Figure 3-1). This sampling was performed to determine the extent of contamination in the sediments due to past disposal activities at OU No. 2. The sediment sampling activities are described in Section 3.1.2.

Some of the samples could not be collected due to sampler refusal, boat access (which required samples to be collected from the shore), and flocculant sediments that would not remain in the sampler. Tables 3-1, 3-2 and 3-3 explain why samples were not collected at some of the stations.

3.2.3.1 Wallace Creek

TCL organics and TAL inorganics were detected in sediment samples collected in Wallace Creek (see Tables 3-11 and 3-12). The data and frequency tables are provided in Appendix E. The following paragraphs summarize the results of the sediment investigation.

Pesticides 4,4'-DDE, 4,4'-DDT, 4,4'-DDD, and dieldrin were detected at seven sediment sample locations. PCB-1260 was detected at seven sediment locations.

The following VOC's were detected at all eleven sediment locations: methylene chloride, acetone, carbon disulfide, 2-butanone, 1,2,-dichloroethene, TCE, toluene, and total xylenes. The following SVOCs were detected in a few of the sediment samples: phenol, diethyl phthalate, phenanthrene, fluoranthene, butyl benzyl phthalate, benzo(a)anthracene, chrysene, bis(2-ethylhexyl) phthalate, pyrene, benzo(b)fluoranthene, benzo(a)pyrene, and benzo(k)fluoranthene. The concentration ranges of the positively detected TCL organics and the sample number with the maximum detection are as follows:

	Sample	Concentration
Constituent	Number	Range (ug/kg)
Dieldrin	WC01-SD-612D	4.8J
4,4'-DDE	WC09-SD-612M	5.9 to 8.3
4,4'-DDD	WC08-SD-06M	7.4J to 200J
4,4'-DDT	WC08-SD-06M	200J to 1,200J
PCB-1260	WC08-SD-06M	31J to 2,100J
Methylene chloride	2WC03-SD-612B	6J to 910J
Acetone	WC09-SD-612B	26 to 24,000J
Carbon Disulfide	WC10-SD-612M	2J to 24J
1,2-Dichloroethene	WC07-SD-06B	31J
2-Butanone	WC09-SD-612B	21J to 9,300
TCE	WC02-SD-06B	7J to 23
Toluene	WC06-SD-06M	4J to 5J
Total xylenes	WC03-SD-06M	26 to 120J
Phenol	WC06-SD-06B	120J to 190J
Diethyl phthalate	WC06-SD-06B	120J to 530J
Phenanthrene	WC08-SD-612M	76J
Flouranthene	WC08-SD-06B	94J to 760J

3-9

Pyrene	WC08-SD-06B	95J to 810J
Butyl benzyl phthalate	WC07-SD-06B	200J to 920J
Benzo(a)anthracene	WC08-SD-06B	67J to 210J
Chrysene	WC08-SD-06B	74J to 230J
Bis(2-ethylhexyl)	WC11-SD-06B	960J
phthalate		
Benzo(b)fluoranthene	WC08-SD-06B	4J to 420J
Benzo(k)fluoranthene	WC08-SD-06B	67J to 140J
Benzo(a)pyrene	WC09-SD-06B	63J to 1,600

Eighteen of 24 TAL inorganics were detected in these sediment samples. Antimony, cadmium, cyanide, mercury, selenium, and thallium were not detected in any of the samples. The concentration ranges of the positively detected TAL inorganics, and the sample number with the maximum detection are as follows:

	Sample	Concentration
<u>Constituent</u>	Number	Range (mg/kg)
Aluminum	WC10-SD-06M	539 to 25,400
Arsenic	WC08-SD-612M	1.0B to 10.2
Barium	WC08-SD-612M	2.5JB to 110
Beryllium	WC07-SD-06B	0.07B to 0.78B
Calcium	WC04-SD-06M	242B to 90,000J
Chromium	WC10-SD-06M	1.2B to 28.5
Cobalt	WC09-SD-06M	06JB to 3.3JB
Copper	WC-03-SD-06M	0.43JB to 53,200
Iron	WC09-SD-06M	390 to 14,600
Lead	WC03-SD-06M	1.5 to 314J
Magnesium	WC11-SD-06M	50.5B to 9840
Manganese	WC09-SD-06M	3.1 to 50.2
Nickel	WC10-SD-06M	2.7JB to 10.7JB
Potassium	WC10-SD-06M	38.5JB to 2,200B
Silver	WC03-SD-06M	7.3
Sodium	WC11-SD-06B	224JB to 18,300
Vanadium	WC10-SD-06M	0.82JB to 45.5J
Zinc	WC03-SD-06B	6.2 to 388

3.2.3.2 Bear Head Creek

TCL organics and TAL inorganics were detected in sediment samples collected in Bear Head Creek (see Tables 3-13 and 3-14). The data and frequency tables are provided in Appendix E. The following paragraphs summarize the results of the sediment investigation.

Pesticides, PCBs, VOCs, and SVOCs were all detected in some of the sediment samples taken in Bear Head Creek. The pesticides 4,4'-DDE, 4,4'-DDT, 4,4'-DDD, and alpha chlordane were detected at five sediment stations. PCB-1260 was detected at four sediment stations.

Several VOCs were detected at all seven sediment locations including methylene chloride, acetone, PCE, 2-butanone, TCE, benzene, ethlybenzene, and total xylenes. The following SVOCs were detected in several samples: 1,4-dichlorobenzene, pyrene, benzo(b)fluoranthene, benzo(a)pyrene, and indeno(1,2,3-cd)pyrene. The concentration ranges of the positively detected TCL organics and the sample number with the maximum detection are as follows:

	Sample	Concentration
<u>Constituent</u>	Number	Range (ug/kg)
4,4'-DDE	BH06-SD-06B	5.7 to 68
4,4'-DDD	BH04-SD-612M	8.4J to 220J
4,4'-DDT	BH04-SD-612M	6.6J to 38J
Alpha chlordane	BH06-SD-06B	14J
PCB-1260	BH04-SD-612M	51 to 370J
Methylene chloride	BH03-SD-612M	2J to 7J
Acetone	BH04-SD-06B	34 to 9,900J
2-Butanone	BH05-SD-06B	3J to 2,600
TCE	BH07-SD-06M	5J to 150
Benzene	BH01-SD-06B	5J
PCE	BH03-SD-06B	3J
Ethylbenzene	BH07-SD-06M	57J
Total Xylenes	BH07-SD-06M	3J to 380
1,4-Dichlorobenzene	BH07-SD-06M	340J to 370J
Pyrene	BH06-SD-06B	60J to 76J
Benzo(b)fluoranthene	BH06-SD-06B	96J
Benzo(a)pyrene	BH06-SD-06B	93J to 640
Indeno(1,2,3-cd)pyrene	BH04-SD-06B	40J

TAL inorganics were detected in all 20 of the sediment samples collected from Bear Head Creek. Eighteen of 24 TAL inorganics were detected in these sediment samples. Antimony, cyanide, mercury, nickel, silver, and thallium were not detected in any of the samples. The concentration ranges of the positively detected TAL inorganic compounds, and the sample number with the maximum detection are as follows:

	Sample	Concentration
<u>Constituent</u>	Number	Range (mg/kg)
Aluminum	BH07-SD-06M	465 to 22,100J
Arsenic	BH07-SD-06B	0.54B to 6.1JB
Barium	BH03-SD-612M	7.7JB to 40.4B
Beryllium	BH03-SD-612B	0.13B to 0.97B
Cadmium	BH07-SD-06M	0.54JB to 4.7JB
Calcium	BH04-SD-06B	1,210 to 45,600
Chromium	BH07-SD-06M	2.3B to 16.4B
Cobalt	BH07-SD-06M	1.7JB to 4B
Copper	BH07-SD-06B	1.2JB to 28.1B
Iron	BH07-SD-06	442 to 17,100J
Lead	BH07-SD-06M	2.5 to 70.4J
Magnesium	BH07-SD-06M	57.6B to 10,500J
Manganese	BH07-SD-06M	3.8J to 48.6
Potassium	BH07-SD-06B	121B to 1,930B
Selenium	BH02-SD-612M	2.9
Sodium	BH07-SD-06B	86.5JB to 36,200J
Vanadium	BH07-SD-06M	1.5JB to 54.1B
Zinc	BH07-SD-06M	6.4B to 82.4

3-12

3.2.3.3 Ravine

TCL organics and TAL inorganics were detected in sediment samples collected from the ravine (see Tables 3-15 and 3-16). The data and frequency tables are provided in Appendix E. The following paragraphs summarize the results of the sediment investigation.

Pesticides 4,4'-DDE, 4,4'-DDT, 4,4'-DDD, endrin, endrin aldehyde, and dieldrin were detected at all eight sediment locations. PCB-1260 was detected at five sediment locations.

Two VOCs (acetone and 2-butanone) were detected at several sediment stations. Twenty different SVOCs were detected in sediment samples. The concentration ranges of the positively detected TCL organic compounds and the sample number with the maximum detection are as follows:

	Sample	Concentration
<u>Constituent</u>	Number	<u>Range (ug/kg)</u>
Dieldrin	RV1-SD-06	8.1J to 43J
4,4'-DDE	RV2-SD-06	23J to 120J
Endrin	RV1-SD-06	5.1J
4,4'-DDD	RV2-SD-06	4.1J to 45J
4,4'-DDT	RV3-SD-06	14J to 210J
Endrin Aldehyde	RV1-SD-06	7.8
PCB-1260	RV1-SD-06	29J to 360J
Acetone	RV4-SD-612	62 to 9,100J
2-Butanone	RV4-SD-612	2300 to 2,400J
Naphthalene	RV2-SD-06	54J
2-Methylnaphthalene	RV2-SD-06	44J
Acenaphthene	RV2-SD-06	220J
Dibenzofuran	RV2-SD-06	110J
Fluorene	RV2-SD-06	250J
Phenanthrene	RV2-SD-06	50J to 1,600
Anthracene	RV2-SD-06	480
Di-n-butyl phthalate	RV7-SD-612	52J
Fluoranthene	RV2-SD-06	84J to 1,500J
Carbazole	RV2-SD-06	170J
Pyrene	RV2-SD-06	96J to 2,100

Benzo(a)anthracene	RV2-SD-06	43J to 1,100
Chrysene	RV2-SD-06	59J to 1,100
Bis(2-ethylhexyl)	RV3-SD-06	200J
phthalate		
Benzo(b)fluoranthene	RV2-SD-06	54J to 1,200
Benzo(k)fluoranthene	RV7-SD-06	440
Benzo(a)pyrene	RV2-SD-06	70J to 1,000
Indeno(1,2,3-cd)pyrene	RV2-SD-06	57J to 710
Dibenz(a,h)anthracene	RV2-SD-06	83J
Benzo(g,h,i)perylene	RV8-SD-06	57J to 680

: ŝ

Nineteen of 24 TAL inorganics were detected in these samples. Antimony, cyanide, selenium, sodium, and thallium were not detected in any of the samples. The concentration ranges of the positively detected TAL inorganics and the sample number with the maximum detection are as follows:

	Sample	Concentration
<u>Constituent</u>	Number	Range (mg/kg)
Aluminum	RV1-SD-06	739 to 10,300
Arsenic	RV1-SD-06	0.61B to 4.3
Barium	RV1-SD-06	2.9JB to 61.5
Beryllium	RV8-SD-06	0.06B to 0.25B
Cadmium	RV1-SD-06	0.53JB to 5.9J
Calcium	RV6-SD-06	148B to 10,100
Chromium	RV1-SD-06	2B to 17.7
Cobalt	RV1-SD-06	0.72B to 2.1JB
Copper	RV1-SD-06	2.6JB to 67.5
Iron	RV1-SD-06	420 to 7,590
Lead	RV8-SD-06	2.1B to 105J
Magnesium	RV1-SD-06	24.5B to 402B
Manganese	RV1-SD-06	3.4J to 288
Mercury	RV1-SD-06	0.03B to 0.75
Nickel	RV1-SD-06	2.1B to 7.7JB
Potassium	RV1-SD-06	29.5B to 361B
Silver	RV8-SD-06	0.56B to 1.2B
Vanadium	RV1-SD-06	1.2B to 19
Zinc	RV1-SD-06	20.3 to 408

3-14

3.3 Extent of Contamination

The following sections describe the extent of surface water and sediment contamination in Wallace Creek, Bear Head Creek, and the ravine.

3.3.1. Surface Water

The following discusses the extent of the contaminants detected in the surface water samples collected from Wallace Creek, Bear Head Creek, and the ravine. Several TCL organics and TAL inorganics were detected in samples collected from these areas.

3.3.1.1 Wallace Creek

VOCs and/or SVOCs were detected in Wallace Creek in sample stations 6-WC3 through 6-WC11. The VOCs were generally detected in higher frequencies and higher concentrations at stations 6-WC7, 6-WC8, and 6-WC9 while the SVOCs were only detected at stations 6-WC5 and 6-WC10. The VOCs in the surface water may be related to contaminated groundwater discharging to Wallace Creek between stations 6-WC6 and 6-WC7. However, the VOC contamination either ends or becomes diluted below detection levels by station 6-WC10. The SVOCs do not appear to be associated with Sites 6 or 82 because they are in low concentrations at two distinct stations.

The following TAL inorganics were detected in similar concentrations in both the upstream and downstream samples: aluminum, iron, manganese, and vanadium. The following TAL inorganics were detected in higher concentrations in the downstream samples, however, this increase is probably due to the increase in saltwater at these stations: calcium, magnesium, potassium, and sodium. The following TAL inorganics were detected in four or less samples and a trend could not be established: arsenic, cadmium, chromium, cobalt, mercury, nickel and silver. The following TAL inorganics were only detected at stations upstream of station 6-WC6: barium and lead. Finally, the following TAL inorganics only were detected at stations 6-WC5, 6-WC10, and 6-WC11: copper and zinc. Overall, there does not appear to be any association of the TAL inorganics in the surface water with contaminants from Sites 6 or 82.

3.3.1.2 Bear Head Creek

Two SVOCs were detected at low concentrations in Bear Head Creek. One SVOC was detected at one station (6-BH07) while the other SVOC was detected at three stations (6-BH01, 6-BH04, and 6-BH05). The SVOCs do not appear to be associated with this site because of the low frequency of detection and the low concentrations.

TAL inorganics were detected at every sampling station at Bear Head Creek. The following TAL inorganics were detected at both upstream and downstream sampling locations and at similar concentrations: aluminum, barium, manganese and iron. The following TAL inorganics were detected at higher concentrations at the downstream sampling locations, however, this increase is probably due to higher saltwater content at these stations: calcium, magnesium, potassium and sodium. The following TAL inorganics were detected only downstream and at low concentrations: chromium, copper, silver, mercury, and zinc. The source of these metals may be related to contamination at OU No. 2 via surface runoff. With the exception of one sample, lead was only detected in the downstream samples. Therefore, it may be associated with contamination at OU No. 2. Vanadium was only detected upstream of 6-BH04 at a low concentration. Finally, nickel was detected in two samples and a trend could not be established. Overall, chromium, copper, lead, mercury, silver and zinc appear to be the only TAL inorganics in Bear Head Creek that may be related to contamination at OU No. 2.

3.3.1.3 <u>Ravine</u>

Acetone was the only VOC detected in the surface water at the ravine. It was only detected once at sampling station 6-RV5. Pesticides, PCBs, and SVOCs were not detected in any of the surface water samples collected in the ravine. Therefore, there does not appear to be any organic contamination at this site since the acetone may be related to field decontamination procedures.

Seventeen of the 23 TAL inorganics were detected in the surface water at the ravine. Eleven TAL inorganics, including aluminum, barium, calcium, copper, iron, lead, magnesium, manganese, potassium, sodium, and zinc were found at stations 6-RV2, 6-RV3, 6-RV5, 6-RV7, and 6-RV8. Barium, aluminum, magnesium, potassium, and zinc appear to have higher concentrations at the lower stations, while iron appears to have a higher concentration at the higher stations. Calcium, copper, lead, and manganese have similar concentrations at all stations. Arsenic, cadmium, chromium, cobalt, silver and vanadium were detected four or less

times and a trend could not be established. The potential sources of contamination in the ravine include drums, containers and batteries observed in the ravine.

3.3.2 Sediments

The following discusses the extent of contaminants detected in the sediment samples collected from Wallace Creek, Bear Head Creek, and the ravine. Several TCL organics and TAL inorganics were detected in samples collected form the areas.

3.3.2.1 Wallace Creek

Pesticides and PCBs were detected at several stations at Wallace Creek. One pesticide (dieldrin) was detected once at an upstream location. 4,4'-DDE, 4,4'-DDD, and 4,4'-DDT were detected downstream at sampling locations 6-WC06 through 6-WC11. PCB-1260 was detected in the sediments at Wallace Creek at stations 6-WC04 through 6-WC11, with the highest concentrations being detected at stations 6-WC06 through 6-WC08. These pesticides and PCBs may be related to past disposal practices at OU No.2.

Eight VOCs and 12 SVOCs were detected in the sediments at Wallace Creek. The VOCs were detected both in upstream and downstream samples with the higher concentrations generally being found in the upstream samples. The SVOCs were detected mainly in downstream samples 6-WC05 through 6-WC11 with only two SVOC detections upstream (butyl-benzyl phthalate at 6-WC04 and benzo(k)fluoranthene at 6-WC01). The SVOCs may be related to the drums of petroleum products observed at OU No.2.

TAL inorganics were found at all sampling stations in Wallace Creek. The following metals were detected in several of the upstream and downstream samples: aluminum, arsenic, barium, calcium, chromium, copper, iron, lead, magnesium, manganese, potassium, sodium and vanadium. Cobalt and zinc were detected mainly in the downstream samples with higher concentrations detected at stations 6-WC08 through 6-WC11. Low concentrations of nickel were detected in one upstream sample and in three downstream samples. Silver was detected once at a low concentration at station 6-WC03. Arsenic, chromium, lead, nickel and zinc were detected in higher concentrations in the downstream samples and there presence may be related to contamination at OU No.2.

3.3.2.2 Bear Head Creek

In Bear Head Creek, pesticides and PCBs were detected in both upstream and downstream samples at stations 6-BH03 through 6-BH06. Alpha chlordane was detected once at station 6-BH07 while 4,4'-DDE, 4,4'-DDD, 4,4'-DDT, and PCB-1260 were detected several times at all of the above stations. The highest pesticide and PCB concentrations were found at station 6-BH04. These pesticides and PCBs may be related to past disposal practices at OU No.2.

Eight VOCs and five SVOCs were detected in the sediments at Bear Head Creek. Acetone, 2butanone, TCE and total xylenes were found in both upstream and downstream samples. Methylene chloride, benzene and PCE were detected at low concentrations only in upstream samples. The highest VOC concentrations (acetone and 2-butanone) were found at stations 6-BH04 and 6-BH05. SVOCs were detected in the downstream samples with benzo(a)pyrene being the only SVOC detected in an upstream sample. The highest SVOC concentration was detected 6-BH03. The acetone and 2-butanone may be related to field decontamination procedures. The other VOCs and SVOCs do not appear to be site related.

TAL inorganics were detected in both upstream and downstream sediment samples. The following TAL inorganics were detected both upstream and downstream with higher concentrations generally detected at the downstream stations: aluminum, arsenic, calcium, copper, iron, magnesium, manganese, potassium, sodium, vanadium, and zinc. Barium, beryllium, cadmium, chromium and lead were detected in both upstream and downstream samples at essentially constant concentrations. Cobalt was detected only in downstream samples and selenium was detected only once in an upstream sample. Overall, none of the metals in Bear Head Creek sediments appeared to be related to site contamination

3.3.2.3 <u>Ravine</u>

Pesticides and PCBs were detected at every sampling station at the ravine except 6-RV8. 4,4'-DDE, 4,4'-DDD, and 4,4'-DDT were detected at stations 6-RV2 through 6-RV7 with the highest concentrations being detected at stations 6-RV2 and 6-RV3. Endrin and endrin aldehyde were detected at low concentrations at station 6-RV2. PCB-1260 was detected at its highest concentration at stations 6-RV1 and 6-RV2. These pesticides and PCBs may be related to past disposal practices at OU No.2.

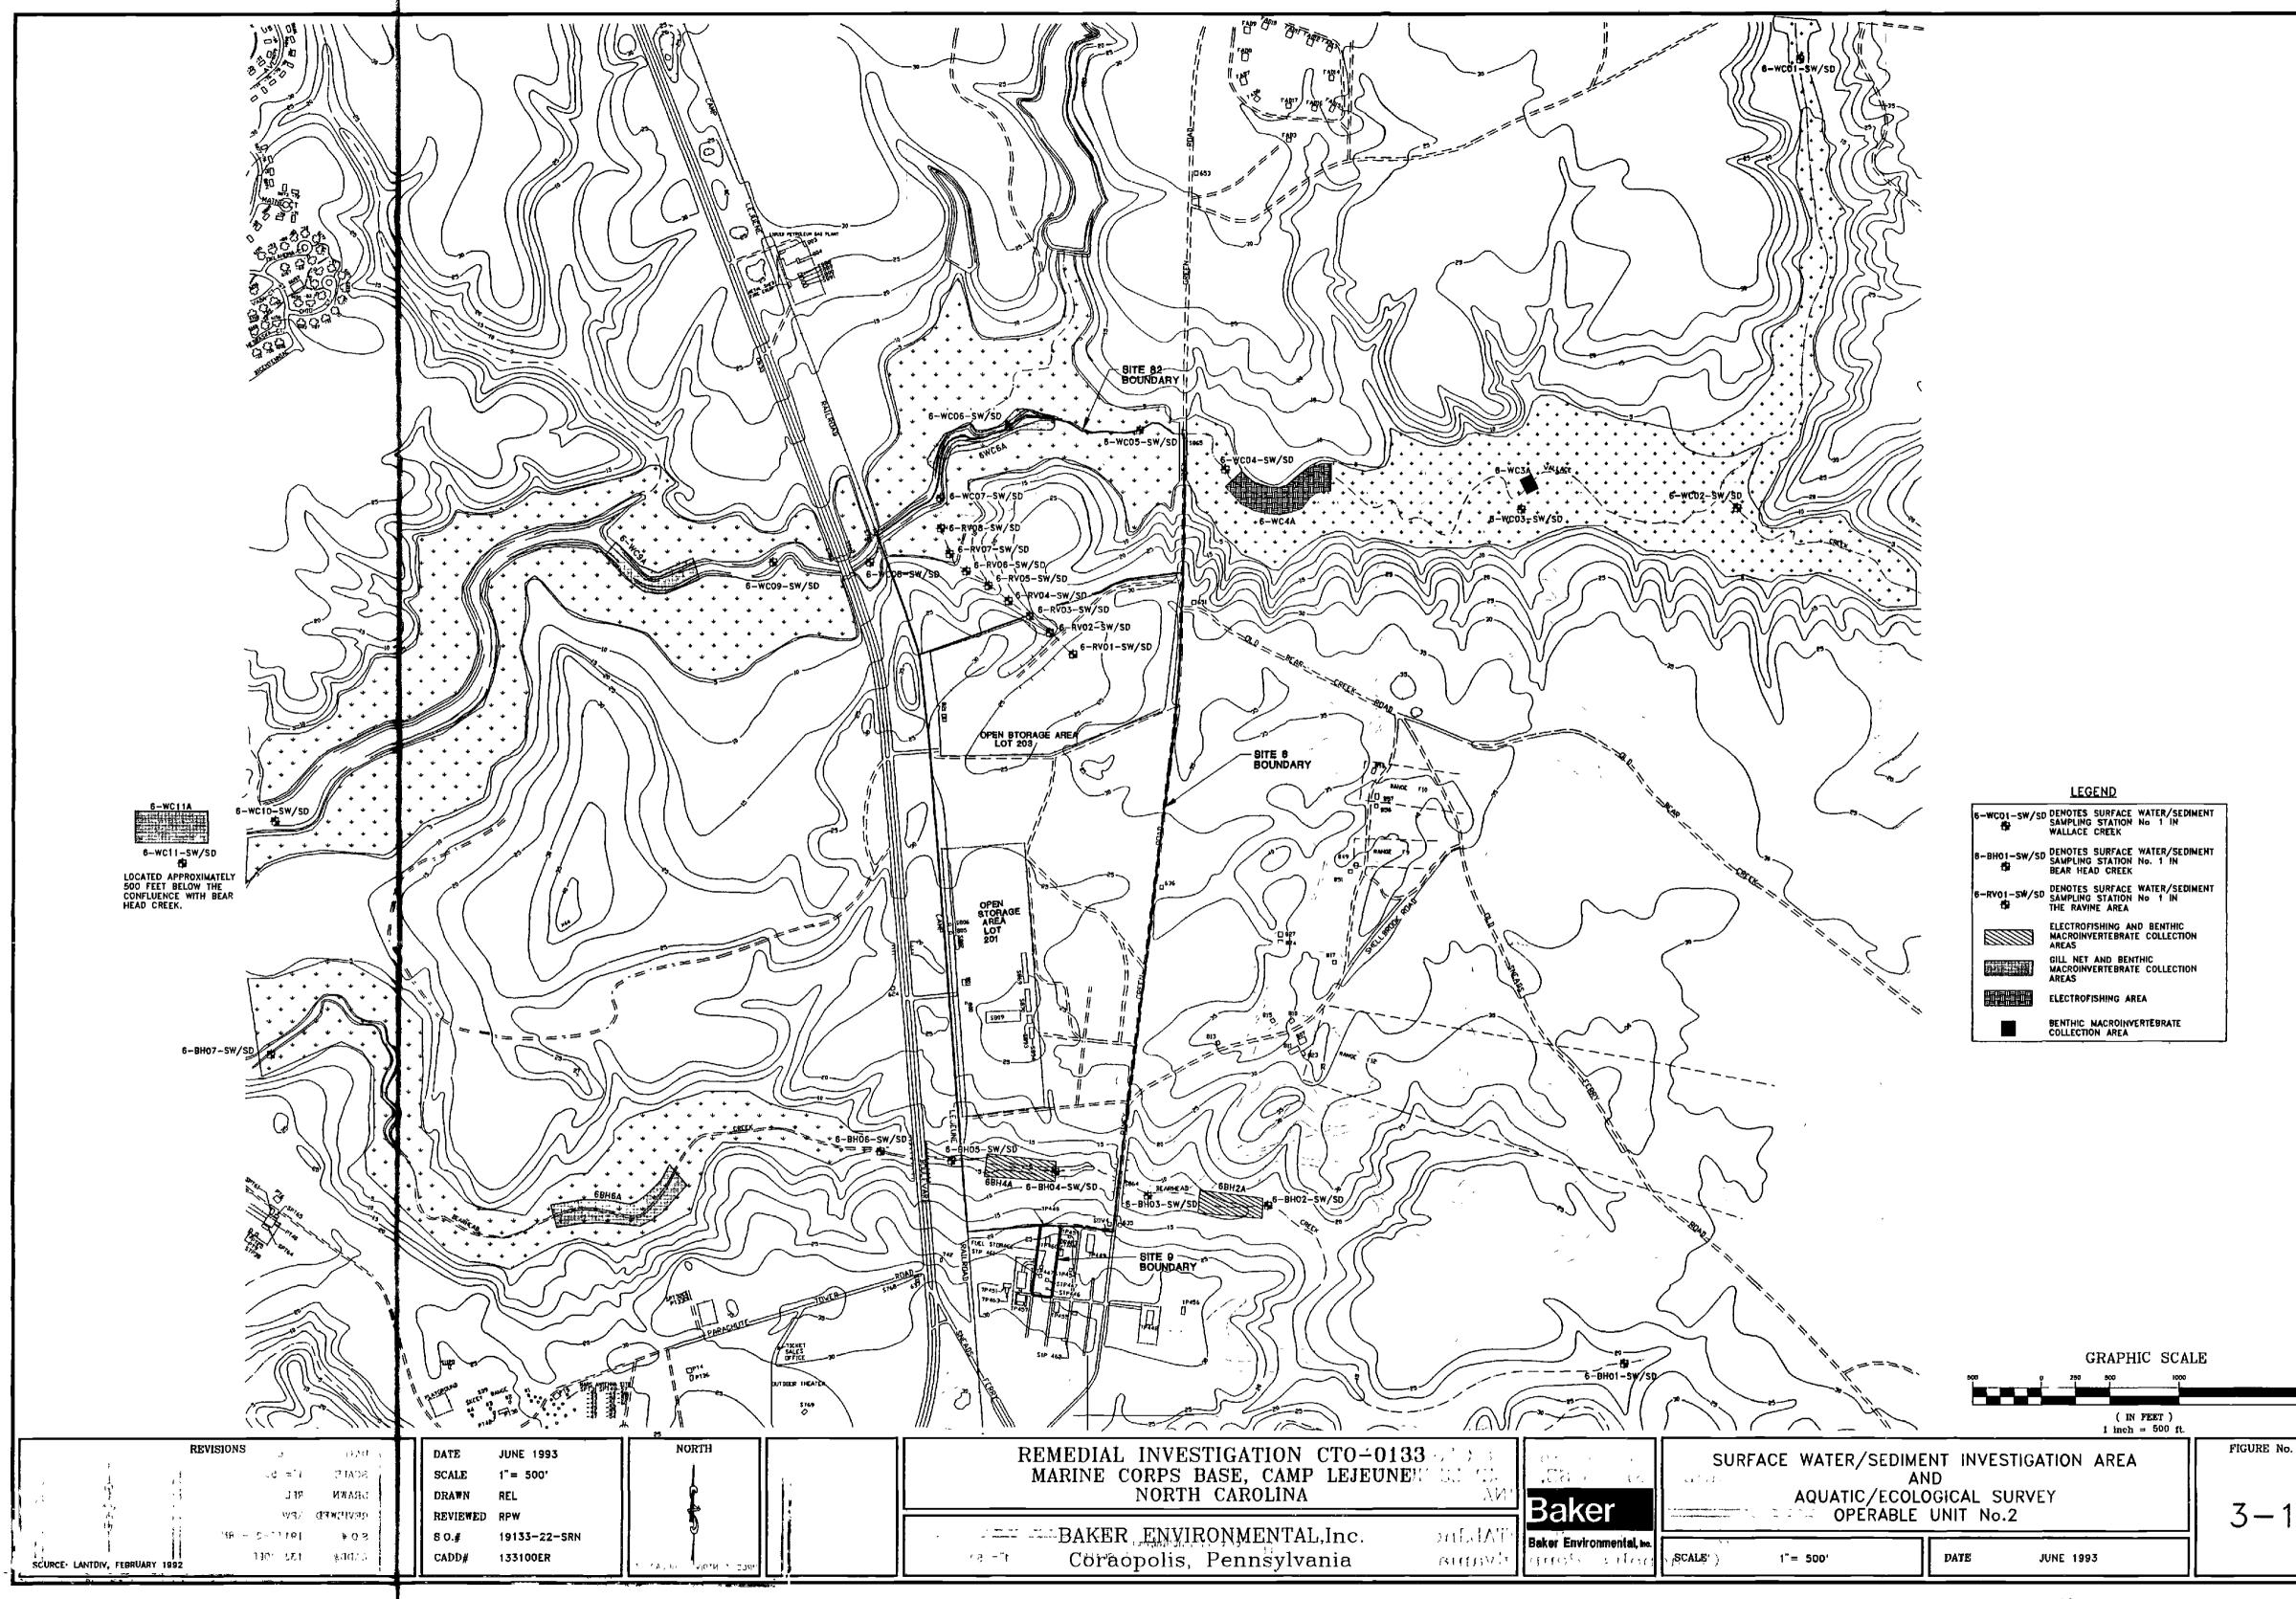

Two VOCs and 20 SVOCs were detected in the sediment at the ravine. The highest VOC concentrations (acetone and 2-butanone) were detected at stations 6-RV4 and 6-RV6. SVOCs were only detected at sampling stations 6-RV1 through 6-RV3 and 6-RV7 and 6-RV8. The highest SVOC (for each SVOC) concentrations were detected in 6-RV2. The acetone and 2-butanone may be related to field decontamination procedures. The SVOCs may be related to past disposal practices at OU No.2.

TAL inorganics were detected at all sampling stations in the ravine. The following TAL inorganics were detected at every station at varying concentrations: aluminum, copper, iron, lead, magnesium, manganese, vanadium and zinc. Cadmium, calcium, and potassium were found at almost every station at essentially constant concentrations. Chromium, mercury, and silver were found at low concentrations throughout the sediments. Arsenic, beryllium, cobalt and nickel were all detected in four or less samples and a trend could not be established. TAL inorganics may be related to past disposal practices at OU No.2.

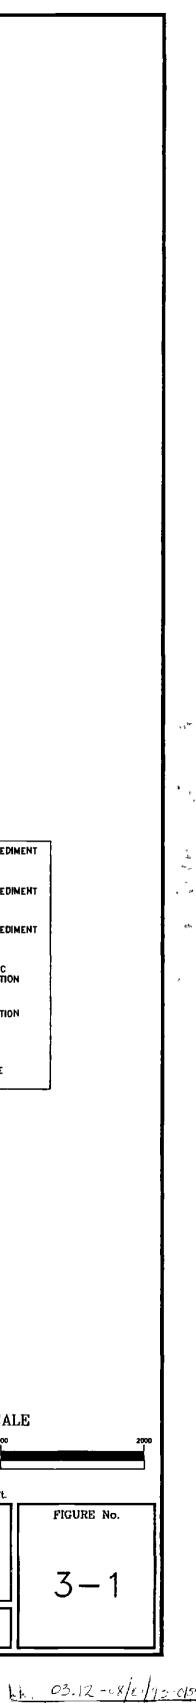

3.4 Contaminant Distribution

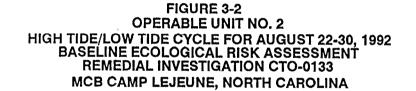

The distribution of contaminants in the surface waters may vary depending on the tides and precipitation events. Concentrations of contaminants in the surface water are expected to decrease with higher tides and precipitation events because of the increased dilution. It also should be noted that the tides may transport contaminants upstream from the point of entry into tidally influenced areas of Wallace Creek and Bear Head Creek. High tide and low tide data was obtained from the National Oceanic and Atmospheric Administration (NOAA) for the New River at Jacksonville, North Carolina. The tide at Jacksonville was obtained by applying a correction factor to data collected from a NOAA tide station in Hampton Roads, Virginia. Table 3-17 contains the low tide and high tide feet and time from August 1 through September 17, 1992, while Figure 3-2 graphically displays the tide data for the days when the surface water samples were collected. In addition Table 3-18 lists if the surface water samples were collected during falling or rising tides.

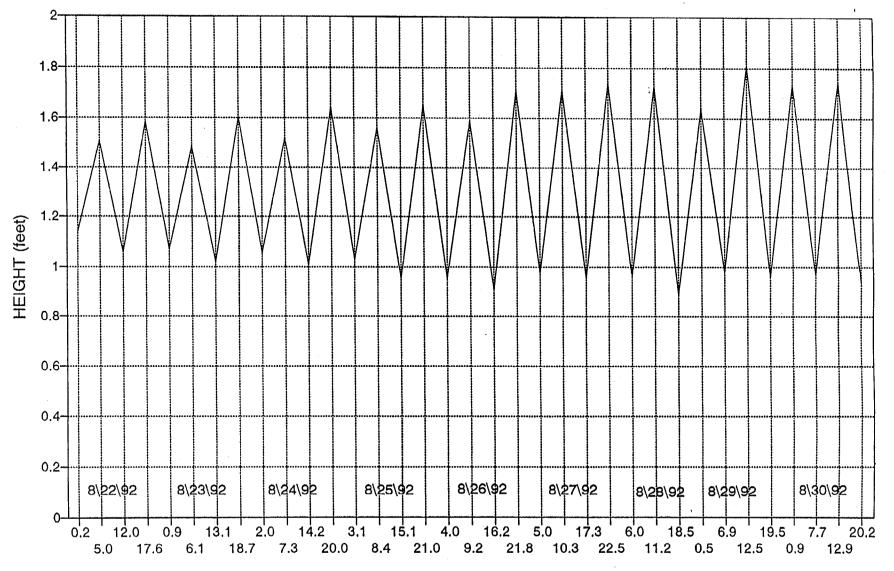

Surface water samples were collected at OU No. 2 from August 22 to August 30, 1992. There was some precipitation approximately one week before the start of the sampling events, and there was no precipitation during the sampling events.

B - Sample was collected from the south bank

M - Sample was collected from the middle of the creek

SW-06 - Sample was collected from the water surface (or mid-vertical point if a deeper water sample was not collected at this station).

SW-312 - Sample was collected from the water/sediment interface

SD-06 - Sample was collected from the top six inches of the sediment

SD-612 - Sample was collected from six to twelve inches of the sediment

(A) - Samples were collected from shore; depth sample could not be collected

(B) - Samples were collected from shore; middle samples could not be collected

(C) - Sampler refusal at 3-4 inches; 6-12 inch sample could not be collected

(D) - Sediments were flocculant; 6-12 inch sample could not be collected

4.0 ECOLOGICAL INVESTIGATION

This section discusses the ecological investigation conducted at OU No. 2. Included in this section are the selection of target species; selection of ecological endpoints; the sampling methodologies, procedures, and station locations; and the sampling results. The sampling included the collection of fish and benthic macroinvertebrate species for population analysis and the collection of fish and crabs for tissue analysis.

4.1 Introduction

The ecological investigation at OU No. 2 was conducted to determine if contamination attributable to OU No. 2 is adversely impacting the ecological integrity of Wallace Creek, Bear Head Creek, or the ravine. The potential impact to the ecological integrity was evaluated by the use of ecological endpoints (described in Section 4.3) in the risk characterization (described in Section 7.0).

Three types of information are needed to evaluate potential links between the contaminants of concern (COCs) and the ecological endpoints. First, chemical analyses of the appropriate media are necessary to establish the presence, concentrations, and variabilities of the COCs. Second, ecological surveys are necessary to establish if adverse ecological effects have occurred. Finally, toxicological information is necessary to evaluate the potential effects of the COCs on the ecological receptors. The combination of all three types of data allows the assessment of the relative contribution of other potential causes of the OCcs, such as habitat alterations and natural variability. Therefore, confidence in cleanup and monitoring decisions is greatly enhanced when based on a combination of chemical, ecological, and toxicological data.

The investigation included the collection of fish and benthic macroinvertebrates for population statistics and fish and crabs for "body burden" analysis. The following describes the methodologies for the biosurvey field work and for the ecological endpoint evaluation.

4.2 <u>Selection of Target Indicator Species</u>

The following sections discuss the target indicator species that were chosen for the ecological risk assessment, and the reason they were chosen as indicator species. The four primary criteria used for the selection of the indicator species are listed below:

- Importance to ecological systems
- Sensitivity
- Availability of practical methods for prediction and measurement
- Trustee species or regulatory endpoint

4.2.1 Fish

Estuaries serve as a unique environment for many marine species of fish. Reduced salinity and lower incidence of piscivorous predators, together with a rich food supply, provide benefits to these fishes. While a few fish spend their entire life cycle in estuaries, most are seasonal members of estuarine communities or utilize this habitat strictly as a migratory pathway between feeding and spawning areas (Kennish, 1990).

Estuarine fish must have the ability to regulate their internal environment to successfully inhabit the fluctuating environment of estuaries, where sudden floods and tidal changes abruptly alter salinity. The dominant estuarine fishes have broad salinity tolerances. Marine fishes are preadapted to reduced salinities, so that when salinity gradually decreases in an estuary, many of them will have little difficulty adapting to it (Kennish, 1990).

Fish are commonly used as target indicator species of water quality conditions for the following reasons (USEPA, 1989c):

• Fish are integrators of community response to aquatic environmental quality conditions. They are the end products of most aquatic food webs and, thus, the total biomass of fishes is highly dependent on the gross primary and secondary productivity of lower organism groups.

- Fish constitute a conspicuous part of the aquatic biota and are recognized by the public for their endangered status. They also represent the end product of protection for most water pollution abatement programs.
- Fish reproduce once per year and complete their entire life cycle in the aquatic environment. Therefore, the success of each year class is dependent upon the quality of the aquatic environment which they inhabit. The success can be evaluated by determining the general condition of the fish community each summer and fall.
- Fish have a relatively high sensitivity to a variety of substances and physical conditions. Both acute toxicity (missing taxa) and stress effects (depressed growth and reproductive success) can be evaluated.
- Fish have a high capacity for bioaccumulating large amounts of chemicals that can be measured.
- Fish can be quickly identified to the species level in the field and there is an abundance of information available for many species concerning their life distribution.

4.2.2 Benthic Macroinvertebrates

Benthic macroinvertebrates are defined as organisms that are large enough to be seen by the unaided eye, and are retained by a U.S. Standard No. 30 sieve (28 meshes per inch, 0.595 mm openings) (USEPA, 1990). They live at least part of their life cycles within or upon available substrates in a body of water or water transport systems (USEPA, 1990).

Benthic macroinvertebrates are important organisms in the trophic food web. They are a primary food source for many fish species and some terrestrial and bird species. Therefore, a decrease in numbers of benthic macroinvertebrates could lead to decreased populations of fish and other species. Also, constituents that tend to bioaccumulate in organisms could be biomagnified in species that ingest benthic macroinvertebrates. The advantages of using benthic macroinvertebrates as target indicator species are as follows (USEPA, 1989c):

• Benthic macroinvertebrates generally have limited migration patterns or they are sessile for periods in their life cycle. Therefore, they are good indicators for site-specific impacts (i.e., upstream-downstream).

- Benthic macroinvertebrates have a relatively short life cycle (one year or more). Therefore, they are good indicators of short-term environmental variations because their sensitive life stages will respond quickly to various stresses, while the overall species community will respond more slowly.
- Benthic macroinvertebrates may be easily identified down to the family level by trained biologists. Degraded conditions often can be detected in the field in a very short time.
- Benthic macroinvertebrates are easily collected with one or two persons using relatively inexpensive equipment. In addition, there is no detrimental effect on the resident biota.
- Benthic macroinvertebrates are abundant in most water bodies.

4.2.3 Other Aquatic Flora and Fauna

Other aquatic fauna (e.g., zooplankton, microorganisms) and aquatic flora (e.g., submerged and floating vegetation, algae, etc.) are present in Wallace Creek and Bear Head Creek. Although these organisms are important in the ecological hierarchy, they were not collected or quantitatively evaluated in this assessment because they will be accounted for in the application of the ecological endpoints.

4.2.4 Terrestrial Fauna

As discussed earlier in this report, several terrestrial faunal species inhabit MCB Camp Lejeune. Because detailed collections and observations of these species were not conducted, population and community parameters for these species were discussed qualitatively in this evaluation. Comparisons of contaminant concentrations in soil to published plant and earthworm toxicity information was used to evaluate potential effects to flora and invertebrate terrestrial species. In addition, estimated daily intakes were calculated and compared to health-base terrestrial reference values to evaluate potential effects to vertebrate terrestrial species.

4.3 <u>Ecological Endpoints</u>

There are two primary types of ecological endpoints: assessment endpoints and measurement endpoints. Assessment endpoints are environmental characteristics, which, if they were found to be significantly affected, would indicate a need for remediation (e.g., decrease in sports/fisheries). Measurement endpoints are quantitative expressions of an observed or measured effect of the contamination of concern. Measurement endpoints may be identical to assessment endpoints (e.g., measurement of abundance of fish), or they may be used as surrogates for assessment endpoints (e.g., toxicity test endpoints). Both types of endpoints were used in the ecological risk evaluation.

The assessment endpoint should be well defined and operational with a subject (e.g., benthic macroinvertebrates) and a characteristic of the subject (e.g., decrease in numbers of benthic macroinvertebrate). An endpoint should be measurable (e.g., numbers of individuals) or predictable from measurements (e.g., toxicity tests), and the endpoint must be susceptible to the contaminant being assessed. Finally, the assessment endpoints should bear some logical relationship to the environmental decisions of concern.

The measurement endpoints must correspond to, or be predictive of, assessment endpoints. In addition, they must be readily measurable, preferably quickly and inexpensively, using existing techniques. Measurement endpoints must take into consideration the magnitude of the contamination (e.g., it would be inappropriate to use abundance of a deer population to assess the effects on a one acre site) and the exposure pathway. The measurement endpoint should be an indicator of effects that are temporally distributed. Low natural variability in the endpoint is preferred to aid in attributing the variability in the endpoint to the contaminant. Measurement endpoints should be diagnostic of the pollutants of interest, as well as broadly applicable to allow comparison among sites and regions. Also, measurement endpoints should be standardized (e.g., standard procedures for toxicity tests). Finally, it is desirable to use endpoints that already are being measured (if they exist) to determine baseline conditions.

Endpoints are divided into four primary ecological groups: individual, population, community, and ecosystem endpoints. Individual endpoints (e.g., death, growth, tissue concentrations) are evaluated through toxicity tests, models, and other methods used to assess the effects on individual organisms. Population endpoints (e.g., occurrence, abundance, reproductive performance) are evaluated to determine presence and absence of species

4-5

through field studies. Community endpoints (e.g., number of species, species diversity) are used to describe the complexity of the community. Finally, ecosystem endpoints (e.g., biomass, productivity, nutrient dynamics) are used to determine the effects between groups of organisms, and between organisms and the environment. Individual, population and community endpoints were evaluated in this assessment. In addition to those endpoints, the following were qualitatively evaluated in this risk assessment: species that are protected under either State or Federal laws and wetlands that are protected under State and/or Federal laws.

The primary goal in deciding upon which ecological endpoints to evaluate was to determine the current effects that the contamination is having on the environment. The endpoints and the indicator species that were evaluated are discussed in the following sections.

4.3.1 Individual Endpoints

This section discusses the individual endpoints that were used in the ERA including water and sediment criteria.

4.3.1.1 Water Criteria

The North Carolina Department of Environment, Health, and Natural Resources (N.C. DEHNR) has promulgated State Water Quality Standards (WQS). These WQS meet the requirements of both Federal and State law. These standards are regulatory values and are enforceable. They are used to evaluate the quality of waters in North Carolina.

The U.S. EPA Region IV Waste Management Division (Region IV) has adopted screening values for chemicals detected at hazardous waste sites (USEPA, 1992b) based on final and draft EPA Water Quality Criteria. These values are intended as preliminary screening tools to review chemical data from hazardous waste sites. Exceedences of the screening level values indicate that there may be a need for further investigation of the site. Acute and chronic Water Quality Screening Values (WQSV) have been developed for several of the chemicals identified during the surface water investigations at OU No. 2.

Contaminant concentrations detected in the surface water at OU No. 2 were compared to both the N.C. DEHNR WQS and Region IV WQSV to determine if there were any exceedences of the established values. In addition, the upper 95% confidence limit was compared to the

4-6

chronic WQSV. A ratio of greater than unity indicates a potential for adverse effects to aquatic life. The upper 95% confidence limit was used to represent the uncertainty associated with any estimate of exposure concentration over the exposure time and exposure area. If the variability in measured concentration values is great and the upper 95% confidence limit was greater than the maximum detected value, the maximum detected value was used in the comparison.

4.3.1.2 Sediment Screening Values

In addition to contaminants in surface water, aquatic organisms can be adversely affected by contaminants in sediments. Sediments tend to be a sink for certain types of toxic substances, with chemical concentrations in sediments often several orders of magnitude higher than their concentrations in the overlying water.

Currently promulgated sediment quality criteria do not exist. Until these criteria are developed, Region IV is using sediment values compiled by NOAA as screening values for evaluating the potential for chemical constituents in sediments to cause adverse biological effects (USEPA, 1992b). The lower ten percentile (Effects Range-Low (ER-L)) and the median percentile (Effects Range-Median (ER-M)) of biological effects have been developed for several of the chemicals identified during the sediment investigations at OU No. 2. If sediment contaminant concentrations are above the ER-M, adverse effects on the biota are considered probable. If contaminant concentrations are between the ER-M and ER-L, adverse effects on the biota are considered possible, and EPA recommends conducting toxicity tests as a followup. Finally, if contaminant concentrations are below the ER-L, adverse effects on the biota are considered unlikely (USEPA, 1992b).

Contaminant concentrations detected in the sediments at OU No. 2 were compared to the Region IV sediment screening values to determine if there were any exceedences in the established values. In addition, the upper 95% confidence limit was compared to the ER-L. A ratio of greater than unity indicates a possibility for adverse effects to aquatic life, and EPA recommends conducting toxicity tests as a follow-up. The upper 95% confidence limit was used to represent the uncertainty associated with any estimate of exposure concentration over the exposure time and exposure area. If the variability in measured concentration values is great and the upper 95% confidence limit was greater than the maximum detected value, the maximum detected value was used in the comparison.

4.3.2 ... Population Endpoints

The population endpoints that were evaluated in this risk assessment included species occurrence and abundance. The numbers and types of species collected from the sampling stations can qualitatively show trends of increasing or decreasing impacts. For example, if few organisms are collected at downstream stations while there is an abundant population in the upstream stations, the downstream ecosystem may be stressed.

Length-frequency distributions of fish of one age tend to follow a normal distribution pattern. By plotting the length of the fish on the X-axis and frequency on the Y-axis, a succession of peaks appears on the graph. A count of the peaks yields an approximation of age, which in many cases suffices only for the first two to four years because of the coalescing of the peaks due to increased dispersion of the data. Although the overlapping in length distribution reduces the reliability of the method for older age groups, it often is used as an effective check on the scale method of age determination. The length-frequency method suffers from several other disadvantages that affect its usage. First, a particular year class of fish may be absent or poorly represented in a sample. Second, size groupings of fish sometimes are not indicative of year classes due to irregular episodes of hatching. Third, a portion of a year class of fish may be equal in age but not in size owing to differential development under variable conditions. Fourth, fish of a certain size tend to school together.

The biological impairment of the fish community may be indicated by an abundance of tolerant species, the absence of intolerant species, and low species abundance. In addition, abnormal growths, lesions, etc., may indicate the fish community is stressed.

Biological impairment of the benthic macroinvertebrate community may be indicated by the absence of generally pollution-sensitive benthic macroinvertebrate, excess dominance by any one particular taxon, and low overall taxa richness (USEPA, 1989b). Benthic macroinvertebrates differ from each other in their relative sensitivity to pollution (e.g., chemicals) and/or natural stresses (e.g., low dissolved oxygen).

4.3.3 Community Endpoints

This section discusses the community endpoints that were used in the ERA including community similarity and species diversity.

4.3.3.1 Community Similarity

Community similarity between stations was measured using two qualitative indices of community similarity, the Jaccard coefficient (S_J) and the S Φ renson index (S_S) . These indices were used to detect changes in the community structure. Stressed communities presumably will have different species than relatively non-stressed communities, given that all other factors are equal. The indices use two possible attributes of the ecosystem, that is whether a species was or was not present in the collected sample. Because these coefficients are based on the number of species collected and not the number of individuals, a few organisms from several taxa could significantly change the similarity value, whereas there may not be an overall significant difference between the communities.

The S_J is better than the S_S at discriminating between highly similar collections and has been used widely in stream pollution investigations. The S_J ranges from 0.0 (dissimilar) to 1.0 (similar) and is calculated using the following equation:

Where:
$$Sj = \frac{a}{a+b+c}$$

a = number of species common to both collections

 $\mathbf{b} = \mathbf{number}$ of species in the first collection but not the second

c = number of species in the second collection but not in the first

The S_S places more emphasis on common attributes, and is better than the S_J at discriminating between highly dissimilar collections. The S_S ranges from 0.0 (dissimilar) to 1.0 (similar) and is calculated using the following equation:

$$Ss = \frac{2a}{2a+b+c}$$

Where a, b, and c are as described above.

4.3.3.2 Species Diversity

The fish and benthic communities were examined using a mathematical expression of community structure called a diversity index (H'). Diversity data are useful because they condense a substantial amount of data into a single value. The Shannon-Wiener function is one of the more commonly used formulas for calculating species diversity. Species diversity was calculated in logarithmic base 10 for the fish and benthic species collected during the ecological investigation using the following equation (Brower, 1977):

Where: $H' = \sum (p_i * \log(p_i))$.

H' = mean species diversity

 $p_i = proportion$ of the total number of individuals occurring in species i.

Typically, in waterways that are unpolluted and contain suitable habitat for aquatic life, H' ranges from three to four, while in polluted rivers or rivers with unsuitable habitat H' generally is less than one (USEPA, 1983). The operative assumption in the interpretation of H' values is that relatively undisturbed environments tend to support communities that consist of a large number of species with no single species present in overwhelming abundance. Many forms of stress tend to reduce diversity by producing an environment that is less desirable for some taxa and therefore giving a competitive advantage to other taxa.

4.3.3.3 Macroinvertebrate Biotic Index

Most of the benthic macroinvertebrates collected during the ecological investigation have been assigned a pollution tolerance rating. The tolerances were obtained from the N.C. DEHNR DEM, Environmental Sciences Branch (Lenat 1993) and the U.S. EPA Environmental Monitoring Systems Laboratory (U.S. EPA 1990). N.C. DEHNR maintains a complete list of benthic macroinvertebrate species collected, or known to occur, in North Carolina on a database called BINDEX. BINDEX contains the species Latin name, order, biotic index (BI), and feeding group. Biotic indices have not been established for estuarine species. The BI ranges from zero to ten; a zero is assigned to taxa found only in unaltered streams of high water quality, and a ten is assigned to taxa known to occur in streams with intermediate degrees of pollution or disturbance. In addition, the U.S. EPA lists many common benthic macroinvertebrate species along with their tolerance to organic wastes, heavy metals and acids (U.S. EPA, 1990).

The Macroinvertebrate Biotic Index (MBI) was developed to provide a rapid stream quality assessment. The index is an average of BI weighted by organism abundance, and is calculated as follows:

Where: MBI = $\sum (n_i * BI)/N$

The sampled benthic macroinvertebrate population will be assigned a general stream/water quality condition based on the MBI value. The five classes and their corresponding MBI values are given below (Lenat, 1993):

Excellent Water Quality	Good Water Quality	Fair Water Quality	Poor Water Quality	Serious Water Quality Problems
3.68-5.24	5.25-5.95	5.96-6.67	6.68-7.70	7.71-9.45

The MBI for the benthic macroinvertabrate stations was calculated using the values listed in BINDEX. When a BI for a specific species was not listed, either the family BI (if available) was used or the species was not included in the MBI calculations.

4.4 <u>Biological Sampling Methodology</u>

Biological samples collected at OU No. 2 consisted of fish, crabs and benthic macroinvertebrates. Prior to initiating the sampling event at each station, the following information describing the site was recorded in the field log book:

- Average width, depth and velocity of the water body
- Description of substrate

- Description of "abiotic" characteristics of the reach such as pools, riffles, runs, channel shape, degree of bank erosion, and shade/sun exposure
- Description of "biotic" characteristics of the reach including aquatic and riparian vegetation and wetlands

Water quality measurements were collected during the benthic macroinvertebrate sampling, at a minimum, and during collection of some of the fish samples. On-site water quality measurements at these stations consisted of temperature, pH, specific conductance, salinity and dissolved oxygen. These measurements were conducted prior to sample collection.

The Remedial Investigation/Feasibility Study, Sampling and Analysis Plan (SAP) for Sites 6,9,48, and 69 limited the sampling references sites to two stations in the White Oak River Basin (Baker, 1992). The SAP also limited the sampling at the references sites to sampling of fish and benthic macroinvertebrate populations and did not include chemical analyses of sediment, surface water, fish tissue or crab tissue samples. One of the stations was to be used as the reference for the stations with higher salinity, and the other was to be used as the reference for the stations with lower salinity. The reference stations were selected to be as ecologically similar to the sampling stations for Site 6 and 9 and Sites 48 and 69. However, because of the wide range of environmental conditions (i.e., salinity and dissolved oxygen) found at Sites 6, 9, 48, and 69, some of the environmental conditions present at the on-site stations could not be replicated using only the two reference stations. The White Oak River reference station was not included in the OU 2 Draft ERA because salinity ranged from 15 to 26 ppt. This station was selected to be representative of the high salinity New River Stations at Site 48.

The White Oak River watershed is smaller than the New River watershed (See Figure 4-1). It begins in the Hoffman Forest and flows approximately 48 miles and empties into the Atlantic Ocean. Approximately 77 percent of the watershed is within the Hoffman Forest and the Croatan National Forest. This watershed has very little development, with Swansboro being the largest town.

The reference fish and benthic macroinvertebrate station for OU No. 2 was established in Pettiford Creek which is located in the White Oak River Basin (See Figure 4-1). This station is similar to the stations in Wallace Creek and Bear Head Creek in that it has a salinity gradient from fresh to mesohaline at its mouth. The use of Pettiford Creek as a reference creek was based on recommendations by the N.C. DEHNR. The White Oak River watershed was recommended due to limited development. Therefore, the station should be representative of an aquatic system with relatively few impacts due to point and non-point sources of pollution of an industrial nature similar to Camp Lejeune.

The Pettiford Creek station was selected to be representative of a creek near the freshwater/saltwater interface (i.e., salt wedge). However, there are reported large fluctuations in salinity in the White Oak River watershed with measured salinities varying by 10 to 15 ppt from week to week at a given station. Therefore, the characteristics of the benthic macroinvertebrate and fish populations could reflect the variation between a freshwater and low salinity estuarine habitat. The sample results reflect the impact of the freshwater/saltwater interface in the low numbers of benthic macroinvertebrates and fish collected, demonstrating the low diversity and density of this ecotene area.

4.4.1 Fish and Crabs

This section discusses collection of the fish and crab samples in Wallace Creek, Bear Head Creek, and Pettiford Creek.

A literature review was conducted to determine the fish species that may potentially be exposed to contaminants in the surface water/sediment exposure pathway. This review included compiling information from State and Federal natural resources agencies. In addition, Baker's experience in sampling similar areas formed a basis for a database of expected species for the area.

Originally, three species of fish were to be sampled, with each species being a representative of one of three trophic (feeding) groups, which included a first order predator, a second order predator, and a third order predator. In addition, a minimum of ten individuals per specie, if available, of adult fish of preferably uniform size were to be composited and analyzed for whole body burden and fillet burden of chemicals, with the same species of fish being sampled from each station. A fish species was successfully collected if the above requirements were satisfied. These requirements were identified to Baker by the U.S. Fish and Wildlife Service as part of the Work Plan review. Sampling variability can prevent the same species of fish from being sampled at each station because either the preferred species was not captured, or adequate numbers of uniform-size individuals were not captured. Therefore, if the preferred species was not successfully collected to satisfy the above requirements, a substitute species was collected that, if possible, exhibiting a similar trophic position in the estuarine ecosystem.

4.4.1.1 Wallace Creek

This section discusses collection of the fish and crab samples in Wallace Creek including the station locations and sampling procedures.

Station Locations

Fish and crabs were collected from four stations in Wallace Creek. One station was located upstream of OU No. 2 (6-WC4A), one station was located adjacent to OU No. 2 (6-WC6A), and two stations were located downstream of OU No. 2 (6-WC9A and 6-WC11A) (see Figure 3-1).

Station 6-WC4A was located on Wallace Creek approximately 100 feet upstream of Piney Green Road. This station was relocated downstream from the proposed station location (see the Sampling and Analysis Plan [SAP] [Baker, 1992]) because debris obstructed upstream boat access during the time of sampling. Station 6-WC6A was located on Wallace Creek between Piney Green Road and Holcomb Boulevard. Station 6-WC9A was located on Wallace Creek approximately 1000-1500 feet downstream of Holcomb Boulevard, while Station 6-WC11A was located on Wallace Creek approximately 500 feet downstream of it's confluence with Bear Head Creek.

Sampling Procedures

Fish were collected in Wallace Creek using gill nets and a boat-mounted electrofisher. The electrofisher was used when the salinity was in the appropriate salinity range. See Table 4-1 for a listing of the sampling procedure used at each station.

The fish sampling via electroshocking was conducted using a Smith-Root, Inc. electrofisher powered by a 5,000-watt portable generator. A DC current was applied utilizing the boat as a cathode and a hand-held electrode as the anode. The length of shocking time per subsection was recorded as seconds of applied current. Stunned fish were collected with one-inch mesh or smaller dip nets handled by members of the field sampling team.

The gill nets were six feet deep by 50 feet long with two-inch square mesh and an approximate twine break strength of 29 pounds. The nets were deployed approximately at the locations shown on Figure 3-1. Weights were attached to the nets to secure them on the bottom of the stream and yellow bouys marked with "Baker Environmental" were attached to the tops of the nets. The nets were deployed in the morning or evening, and they were checked for fish within twelve hours after deployment.

The collected fish species were identified, measured, and counted. The small fish (less than 20 mm) were weighed in groups of 10 or 20 because of their low individual weight; the larger fish were weighed individually. In addition, blue crabs that were captured in the gill nets were collected, measured, and weighed. The proportion of individuals as hybrids and the proportion of individuals with disease, tumors, fin damage, and skeletal anomalies was recorded at each station.

Most of the fish species were processed in the field and returned alive to the creeks. Some specimens that presented taxonomic difficulties were preserved in 10% formalin and transported to the Baker Ecological Services Laboratory for taxonomic work. At a minimum, one representative fish from each species was preserved in 10% formalin as a voucher specimen.

An attempt was made to collect ten individuals from three different species with each species being a representative of one of the three trophic groups for the tissue analysis. However this success rate was not achieved at any of the stations. The fish were placed individually into clean ziploc or plastic garbage bags and stored on ice for whole body or fillet tissue analysis. The blue crabs were placed individually into clean ziploc bags and stored on ice for whole-body analysis. The bags were labeled with the date and station location. The fish and crabs were frozen prior to being shipped to Ceimic, Inc. for chemical analysis. Table 4-2 shows the number and total weight of the fish and blue crab samples sent to Ceimic.

4.4.1.2 Bear Head Creek

This section discusses collection of the fish and crab samples in Bear Head Creek including the station locations and sampling procedures.

Station Locations

Fish and crabs were collected from three stations in Bear Head Creek. One station was located upstream of OU No. 2 (6-BH2A), one station was located adjacent to site OU No. 2 (6-BH4A), and one station was located downstream of OU No. 2 (6-BH6A) (see Figure 3-1).

Station 6-BH2A was located on Bear Head Creek approximately 1,000 feet upstream of Piney Green Road. This station was located further downstream than proposed in the sampling and analysis plan (Baker, 1992) because the proposed sampling location could not be accessed due to vegetation overgrowth. Station 6-BH4A was located on Bear Head Creek between Piney Green Road and Holcomb Boulevard. Finally, Station 6-BH6A was located on the Bear Head Creek approximately 1,500 to 2,000 feet downstream of Holcomb Boulevard.

Sampling Procedures

Fish were collected in Bear Head Creek using gill nets and a backpack electrofisher. The electrofisher was used when the salinity was in the appropriate salinity range for use of the electrofisher. See Table 4-1 for a listing of the sampling procedures used at each station.

The fish sampling via electroshocking was conducted using a Smith-Root, Inc. electrofisher powered by a 300-watt portable generator. A DC current was applied utilizing a "rattail" as the cathode and a hand-held electrode as the anode. Blocking seines were placed downstream and upstream of the shocking areas to aid in the collection of the fish. The length of shocking time per subsection was recorded as seconds of applied current. Stunned fish were collected with one-inch mesh or smaller dip nets handled by members of the field sampling team.

Gill nets, similar to those used in Wallace Creek, were used to collect fish in Bear Head Creek. The same sample collection and sample processing procedures used in Wallace Creek were conducted in Bear Head Creek. Fish that were collected were processed for population statistics and tissue analysis.

4.4.1.3 Ravine

The ravine receives only runoff from Sites 6 and 82 and therefore, it is only intermittent in nature. No fish collection was proposed for this area in the SAP (Baker, 1992).

4.4.1.4 Pettiford Creek

This section discusses collection of the fish and crab samples in Pettiford Creek including the station locations and sampling procedures.

Station Location

The fish station was located upstream on Pettiford Creek where the salinity was close to zero. See Figure 4-1 for approximate sample location. Several locations with good electrofishing potential (based on salinity) were shocked, however, the yield was very low. Gill nets were not proposed for this station in the SAP (Baker, 1992).

Sampling Procedures

Fish were collected in Pettiford Creek using a boat-mounted electrofisher. The same sample collection and sample processing procedures used in Wallace Creek were conducted at the Pettiford Creek station. All fish that were collected were processed for population statistics; no fish at this station were collected for tissue analysis.

4.4.2 Benthic Macroinvertebrate

This section discusses collection of benthic macroinvertebrate samples in Wallace Creek, Bear Head Creek, and Pettiford Creek.

4.4.2.1 Wallace Creek

This section discusses collection of the benthic macroinvertebrate samples in Wallace Creek including the station locations and sampling procedures.

Station Locations

Benthic macroinvertebrates were collected from four stations in Wallace Creek. One station was located upstream of OU No. 2 (6-WC3A), one station was located adjacent to OU No. 2 (6-WC6A), and two stations were located downstream of OU No. 2 (6-WC9A and 6-WC11A) (see Figure 3-1).

Station 6-WC3A was located on Wallace Creek approximately 3,000 to 4,000 feet upstream of Piney Green Road. At the time this sample was collected, the path in the water was not being obstructed as it was when the fish sample was collected. Station 6-WC6A was located on Wallace Creek, between Piney Green Road and Holcomb Boulevard. Station 6-WC9A was located on Wallace Creek approximately 1,000-1,500 feet downstream of Holcomb Boulevard, and Station 6-WC11A was located on Wallace Creek approximately 500 feet downstream of its confluence with Bear Head Creek.

Sampling Procedures

Benthic macroinvertebrates were collected from a boat using a standard ponar grab. The dimensions of the ponar are $23 \times 23 \text{ cm} (9 \times 9 \text{ in.})$ for a sampling area of 529 cm^2 or 0.0529 m^2 (81 in²).

The ponar was deployed from the boat, which was positioned in slightly different locations for each replicate to prevent the ponar from re-sampling the same area. After retrieving the ponar with a sediment sample, it was opened into a clean tub and the sediments were removed with a teflon spatula. The sediments were transferred to a 0.5 mm sieve that was agitated (by hand) in a tub half-full of water to remove the small particles. The remaining contents in the sieve were transferred into 16-ounce plastic sample jars. The jars were filled up to one-half full with sediments and buffered formalin solution (10% by weight) was added to the remainder of the jar to preserve the benthic macroinvertebrates contained in the sediments. A 100% cotton paper label, marked in pencil with the sample number, was placed inside the jar. The outside of the jar was labeled with the sample number using a black permanent marker to identify the sample containers.

After all the benthic sampling at OU No. 2 was completed, the sample jars were transported to the Baker Ecological Laboratory for sample processing. Sample processing included washing each sample through a 0.5 mm sieve, transferring the washed sample back into the jar, and adding 70% isopropyl alcohol, as a preservative, to the washed sample in the jar. A small amount of rose bengal was added to each jar to stain the benthic macroinvertebrates a pinkred color to aid in the sorting process. The rose bengal stains the tissue cells of the organisms and helped to distinguish them from plant and other materials in the sediments. The benthic macroinvertebrates were stained for at least 24 hours prior to sorting under a dissecting microscope. The benthic macroinvertebrates were removed from the sediments using a pair of forceps, and placed into glass vials containing 70% isopropyl alcohol and a 100% cotton paper label marked in pencil with the sample number. A one-fourth aliquot of sample 6-WC3A was sorted because of its large sample volume. The number of individuals from that aliquot was multiplied by four to obtain the total number of individuals in the sample. The vials were sealed with cotton and placed into a jar containing 70% isopropyl alcohol. The date, sorting time, approximate number of benthic macroinvertebrates collected, and the name of the person who sorted the sample were recorded on a sample processing log sheet.

The same sorting procedures outlined above were repeated as a QA/QC measure, with any additional species identified being placed into their respective vials. A senior environmental scientist was employed to perform this QA/QC measure. Fifty-percent of a sample was resorted. If more than five percent of the individuals were missed during the initial sorting, than the rest of the sample was resorted. If less than five percent of the individuals were missed during the initial sorting, than the rest of the sample was not resorted.

The date, sorting time, number and type of additional organisms found and percent of sample that was QA/QCed were recorded on the sample processing log sheet. The vials containing the benthic macroinvertebrates were sent to RMC Environmental Services for taxonomic identification.

4.4.2.2 Bear Head Creek

This section discusses collection of the benthic macroinvertebrate samples in Bear Head Creek including the station location and sampling procedures.

Station Locations

Benthic macroinvertebrates were collected from three stations in Bear Head Creek. One station was located upstream of OU No. 2 (6-BH2A), one station was located adjacent to OU No. 2 (6-BH4A), and two stations were located downstream of OU No. 2 (6-BH6A) (see Figure 3-1).

Station 6-BH2A was located on Bear Head Creek approximately 1,000 feet upstream of Piney Green Road. This station was located further downstream than proposed in the SAP (Baker, 1992) because the proposed location could not be accessed due to vegetation overgrowth. Station 6-BH4A was located on Bear Head Creek between Piney Green Road and Holcomb Boulevard. Finally, Station 6-BH6A was located on Bear Head Creek, approximately 1,500-2,000 feet downstream of Holcomb Boulevard.

Sampling Procedures

Benthic macroinvertebrates were collected using the same procedures used in Wallace Creek. The only deviation from the procedures occurred at Stations 6-BH2A and 6-BH4A. The ponar samples collected at these stations were collected by standing in the creek and releasing the ponar, as opposed to deploying the ponar from the boat. The sample processing procedures remained the same for these samples.

A one-fourth aliquot of sample 6-BH6A was sorted because of its large sample volume. The number of individuals from that aliquot was multiplied by four to obtain the total number of individuals in the sample.

4.4.2.3 Pettiford Creek

This section discusses collection of the benthic macroinvertebrate samples in Pettiford Creek including the station location and sampling procedures.

Station Locations

The benthic macroinvertebrate station was located upstream on Pettiford Creek where the freshwater and saltwater interface was field measured. See Figure 4-1 for approximate sample location.

Sampling Procedures

Benthic macroinvertebrates were collected in Pettiford Creek using the ponar grab deployed from the boat. The same sample collection and sample processing procedures used in Wallace Creek were conducted at the Pettiford Creek station.

4.5 Site Specific Ecology

The following sections present the results of sampling the abiotic habitat and biotic communities from the ecological investigation.

4.5.1 Abiotic Habitat

Information describing the abiotic habitat at OU No. 2 was recorded in the field log books at each station and was later transferred to data sheets (see Appendix F). The data sheets also include representative photographs of the stations.

4.5.1.1 Fish Stations

Fish were sampled at four stations in the Wallace Creek and three stations in Bear Head Creek (see Figure 3-1). Fish also were sampled at one station in Pettiford Creek (see Figure 4-1).

Wallace Creek

The bank along Station 6-WC4A was lined with shrubs. There was some submerged aquatic vegetation (SAV) present. The water at this station was approximately 2.5 feet deep and the channel was 40 feet wide. The fish collection station consisted of an approximately 120 foot sampling reach which was fished using the boat electrofisher.

Station 6-WC6A was surrounded by deciduous trees and evergreens, with some deadfall. The water at this station was approximately 2.5 feet deep and the channel was 50 feet wide. There was a slight water flow from east to west.

Station 6-WC9A was surrounded by deciduous trees and evergreens, with some deadfall. The water at this station was approximately 12 feet deep and the channel was approximately 75 feet wide. There were no pools or riffles at this station. The water velocity was negligible due to tides.

Station 6-WC11 was surrounded by deciduous trees and evergreens, with some deadfall. The water at this station was approximately six feet deep and the channel was approximately 250

feet wide. There were no pools or riffles at this station. The water velocity was negligible due to tides.

Bear Head Creek

The fish collection station at 6-BH2A consisted of an approximately 120 foot sampling reach that was fished using the backpack electrofisher. The bank was lined with hardwood trees and dense vines. No SAV were present at this station. The water at this station was less than six inches deep and the channel was five feet wide.

The fish collection station at 6-BH4A consisted of an approximately 150 foot sampling reach that was fished using the backpack electrofisher. The bank was lined with deciduous trees. The water at this station was less than six inches deep and the channel was 12 feet wide.

The bank along Station 6-BH6A was lined primarily with deciduous trees and some pines and there was a zone of dead trees and bushes. Some SAVs were was present at this station. The water at this station was approximately 12 feet deep and the channel was approximately 75 feet wide.

Pettiford Creek

The bank along Station PC was lined primarily with conifers, hardwood trees, shrubs and Spanish moss. Some SAV were present at this station. The water at this station was approximately five feet deep and the channel was approximately 15 feet wide.

4.5.1.2 Benthic Macroinvertebrate Stations

Benthic macroinvertebrates were collected from four stations in the Wallace Creek and three stations in Bear Head Creek (see Figure 3-1). Benthic macroinvertebrates also were collected from one station in Pettiford Creek (see Figure 4-1). The following sections discuss the sediment type at each station. The abiotic habitat and biotic communities are discussed in the previous sections of this report.

Wallace Creek

Between 32 to 72 ounces of sediments were collected for the replicates at Station 6-WC3A. Approximately eight ounces of sediments were collected for the replicates at Station 6-WC6A. The sediments did not have a discernable odor. They were silty/sandy with approximately five percent woody debris.

At Station 6-WC9A, approximately eight ounces of sediments were collected in each replicate. The sediment had a strong anaerobic odor and was approximately ninety-five percent silt, with five percent detritus. A salt wedge was recorded at this station as discussed below in Section 4.5.1.

At Station 6-WC11A, approximately eight to sixteen ounces of sediments were collected in the replicates. The sediments had a slight anaerobic odor and were a very silty dark brown organic muck. A salt wedge was recorded at this station.

Bear Head Creek

Between 16 to 48 ounces of sediments were collected for the replicates at Station 6-BH2A. There was no odor to the sediments that were sandy with leaf and twig debris.

Approximately eight ounces of sediments were collected for the replicates at Station 6-BH4A. There was no odor in the sediments that were very silty/sandy.

Between 48 and 88 ounces of sediments were collected for the replicates at Station 6-BH6A. There was a slight anaerobic odor in the sediments that were approximately 60 percent silt and 40 percent organic debris.

Pettiford Creek

Approximately eight ounces of sediments were collected for the replicates at Station PC-BN. There was no odor in the sediments that were hard with approximately 50 percent silt/sand and 50 percent organic debris.

4.5.1.3 <u>Water Quality</u>

Table 4-3 summarizes the field water quality measurements collected at the biological stations. Water quality measurements were collected from the surface and bottom of the creek at representative stations.

A salt wedge was observed at Stations 6-WC9A and 6-WC11A with the salinity at the surface being 0.5 ppt, while the salinity at the bottom was 6 ppt and 7.5 ppt, respectively. The conductivity ranged from 900 to 1,500 micromhos/cm at the surface to 10,900 to 11,500 microhms/cm at the bottom. The dissolved oxygen also followed a similar trend at these stations being 5.1 mg/l and 4.45 mg/l at the surface and 0.13 mg/l and 0.15 mg/l at the bottom, respectively. Heavy rains occurred on the day previous to the sampling at Station 6-WC11A.

The salinity at the remaining stations was non-detectable and the conductivity ranged from 20 to 145 micromhos/cm. The dissolved oxygen at these stations ranged from 3.0 to 6.45 at the bottom and from 5.0 to 5.85 at the surface, The pH ranged from 5.5 to 6.4 S.U. at these stations, while the temperature ranged from 22 to 26 degrees C.

At Pettiford Creek, the conductivity was 270 microhoms/cm, the dissolved oxygen ranged from 3.1 to 7.95 mg/l, and the temperature was 22 degrees C. The salinity at several of the potential sampling stations in Pettiford Creek ranged from non-detectable to 1.5 ppt.

4.5.2 Biotic Community

The following sections present the results of the fish, crab and benthic macroinvertebrate sampling.

4.5.2.1 Fish

Population Statistics

A list of the fish species, the stations where they were collected, and a characterization of each species is presented in Table 4-4. The characterization includes the feeding guild, United States average length of the fish, the type of water where the species is typically found, the migration habits of the species, and the spawning periods and tolerance levels of the species.

Wallace Creek

Fish were sampled with gill nets and/or a boat-mounted electrofishier at four stations in Wallace Creek between August 28, 1992 and September 9, 1992. However, fish collection was unsuccessful at Station 6-WC9A. The fish captured in the gill nets were processed either for population statistics or tissue analysis. The quantity of fish per species, and the average, minimum and maximum length and weight of the fish per station collected from Wallace Creek are reported in Table 4-5.

Eleven fish species were collected in Wallace Creek. The percentage abundance of these species is listed below.

Common Name	<u>Latin Name</u>	<u>Percent</u>
Shiner sp.	<u>Notropis</u> sp.	36
Eastern mosquito	<u>Gambusia affinis</u>	20
Pumpkinseed	<u>Lepomis gibbosus</u>	17
American eel	Anguilla rostata	8
Bluespoted sunfish	Enneacanthus gloriosus	8
Spot	<u>Leiostomas xanthurus</u>	5
Pirate perch	Aphredoderus sayanus	2
Warmouth	<u>Lepomis gulosus</u>	2

Sunfish sp. variesLargemouth bassMicropterus salmoidesSummer flounderParalichthys dentatus

2 for these three species

The abundance of fish was highest at Station 6-WC6A. Of the eleven species that were evaluated at Wallace Creek, the average length of ten of the species was less than approximately one-half of the documented average length of that species. Spot and sunfish could not be compared to the average United States length because either the species could not be determined or the value was not available. Figures 4-2 through 4-6 graphically display the size class distribution for the predominant species in Wallace Creek (American eel, shiner, eastern mosquito, pumkinseed, spot). The distributions are skewed to the left, indicating the species populations are dominated by juveniles. The comparison of species length in Wallace Creek compared to the United States average also supports this theory. Stations 6-WC4A and 6-WC11A demonstrated low species diversity; however, 6-WC6A had an above average species diversity value. The species diversities can be found in Table 4-6.

As the fish were being processed for population statistics or tissue analysis, they were visually inspected for any anomalies such as fin rot and skeletal abnormalities. The species in Wallace Creek did not exhibit any physical anomalies.

Bear Head Creek

Fish were collected either with gill nets and/or a backpack electrofisher at three stations in Bear Head Creek between August 27, 1992 and September 9, 1992. However, fish collection was unsuccessful at Stations 6-BH2A, and 6-BH4A. The fish captured were processed either for population statistics or tissue analysis. The quantity of fish per species, and the average, minimum and maximum length and weight of the fish per station collected from Bear Head Creek are reported in Table 4-5.

Six fish species were collected in Bear Head Creek. The percentage abundance of these species is listed below.

<u>Common Name</u>	<u>Latin Name</u>	<u>Percent</u>
Eastern mosquito	<u>Gambusia affinis</u>	82
Spot	<u>Leiostomas xanthurus</u>	11
Pumpkinseed	<u>Lepomis gibbosus</u>	4
Bluespoted sunfish	<u>Enneacanthus gloriosus</u>	3.0 for these
Bay anchovy	<u>Anchoa mitchili</u>	three species
Killifish	<u>Fundulus</u> sp.	

The sampling efforts at Stations 6-BH2A (upstream station) and 6-BH4A (adjacent station) were not successful. Station 6-BH6A was the only station that fish were successfully collected. Of the six species that were evaluated at Bear Head Creek, the average length of three of the species was less than approximately one-half of the documented average length of that species. Two of the species (bluespoted sunfish and killifish) were within the upper half of the average U.S. range. Spot could not be compared to the average United States length because a length was not available. Figures 4-2 through 4-6 graphically display the size class distribution for the predominant species in Bear Head Creek. A size class distribution pattern could not be

distinguished due to inadequate numbers of fish. Station 6-BH6A had a species diversity of 0.29 (see Table 4-6).

As the fish were being processed for population statistics or tissue analysis, they were visually inspected for any anomalies such as fin rot and skeletal abnormalities. The species in Bear Head Creek did not exhibit any physical anomalies.

Pettiford Creek

Fish were collected with a boat-mounted electrofisher at one station in Pettiford Creek on September 15, 1992. The fish captured by electrofishing were processed for population statistics. The quantity of fish per species, and the average, minimum and maximum length and weight of the fish per station collected from Pettiford Creek are reported in Table 4-5.

Three fish species were collected in Pettiford Creek. The percentage abundance of these species is listed below.

Common Name	Latin Name	Percent
Pumpkinseed	Lepomis gibbosus	50
Shiner sp.	<u>Notropis</u> sp.	25
Striped mullet	<u>Mugil cephalus</u>	25

Of the three species that were collected in Pettiford Creek, the average length of one of the species (shiner) was less than approximately one-half of the documented average length of that species. One of the species (pumpkinseed) was within the upper half of the average United States range. The striped mullet that was captured at Station PC was above the national average for that particular species. Figures 4-2 through 4-6 graphically display the size class distribution for the predominant species in Bear Head Creek. Only a few fish were captured in the Pettiford Creek, therefore, an evaluation regarding the size class distribution could not be determined.

Station PC demonstrated a moderate species diversity. The species diversity value can be found in Table 4-6.

As the fish were being processed for population analysis, they were visually inspected for any anomalies such as fin rot and skeletal abnormalities. The species in Pettiford Creek did not exhibit any physical anomalies.

Similarity Index

The species community similarity between the stations were calculated for fish collected in Wallace Creek, Bear Head Creek and Pettiford Creek (see Table 4-7). The S_J between the Wallace Creek stations ranged from 0 (between several stations) and 0.30 (between Station 6-WC4A and Station 6-WC6A), while the S_S ranged from 0 (between several stations) and 0.46 (between Station 6-WC4A and Station 6-WC6A).

The S_J between Pettiford Creek and Wallace Creek ranged from 0 (between Station 6-WC9A and PC) and 0.25 (between Station 6-WC11A and PC), while the S_S ranged from 0 (between Station 6-WC9A and PC) and 0.33 (between Station 6-WC6A and PC). The S_J between Pettiford Creek and Bear Head Creek (Station 6-BH6A) was 0.13, while the Ss between these stations was 0.22. The S_J between Wallace Creek and Bear Head Creek ranged from 0 (between several stations) and 0.53 (between Station 6-WC6A and Station 6-BH6A), while the S_S ranged from 0 (between several stations) and 0.33 (between Station 6-WC6A and Station 6-BH6A).

The results of these similarity index calculations showed that the stations were not very similar with regards to species composition. The highest similarity (0.5 to 0.6) did not indicate very similar species compositions.

Fish and Crab Tissue Analysis

Fish and crab samples collected in Wallace Creek and Bear Head Creek were analyzed for tissue contaminant concentrations. The fish were analyzed either for fillet or whole body burden and the crabs were analyzed for whole body burden. Table 4-2 shows the number and weight of the fish and crabs sent to Chemic for chemical analysis.

Wallace Creek

Four species (warmouth, pumpkinseed, long-nosed gar, and striped mullet) from station 6-WC6A were submitted for tissue analyses. Two species (summer flounder and blue crab) from station 6-WC11A were submitted for tissue analyses.

Table 4-8 summarizes the results of the TCL organics detected in the fish and crab tissues at OU No. 2. Appendix G contains the data and frequency tables. The maximum concentration of the positively detected TCL organics in the fish or crab tissue, and the sample of the maximum detection, are as follows:

Constituent	Sample Number	Concentration (ug/kg)
Acetone	6-WC11-FL1	280J
Benzene	6-WC11-FL1	5J
2-Butanone	6-WC11-BC	15
	6-WC6-PS	15J
4,4'-DDE	6-WC6-WM1	180
4,4'-DDD	6-WC11-FL1	8.8J
4,4'-DDT	6-WC6-PS	4.9J
Dimethyl phthalate	6-WC11-FL1	86
Endrin	6-WC6-PS	5.4J
Endosulfan II	6-WC6-PS	12J
Methylene Chloride	6-WC11-BC	32
PCB-1260	6-WC06-SMF	1,000J
Phenol	6-WC11-BC	2,500
Toluene	6-WC6-PS	3J
Trichloroethene	6-WC11-BC	15
	6-WC6-SMF	5 J

Table 4-9 summarizes the results of the TAL inorganics detected in the fish and crab tissues at OU No. 2. Appendix G contains the data and frequency tables for these chemicals. The maximum concentration of the positively detected TAL inorganics in the fish or crab tissue, and the sample of the maximum detection are as follows:

<u>Constituent</u>	Sample Number	Concentration (mg/kg)
Beryllium	6-WC11-BC	0.005B
Calcium	6-WC11-BC	29,100J
Magnesium	6-WC11-BC	1,410
Potassium	6-WC06-SMF	3,450
Selenium	6-WC11-BC	0.38
Silver	6-WC11-BC	0.18
Sodium	6-WC11-BC	2,170
Zinc	6-WC6-PS	27.3

Bear Head Creek

Station 6-BH6A was the only station on Bear Head Creek that produced enough fish for tissue analyses. One species (pumpkinseed) from station 6-BH6A-FS was submitted for whole-body tissue analyses.

Table 4-8 summarizes the results of the organic chemicals detected in the fish and crab tissues at Sites 6 and 9. Appendix G contains the data and frequency tables for these chemicals. The maximum concentration of the positively detected TCL organics in the Pumpkinseed tissue are as follows:

Concentration (mg/kg)
350J
5.4J
6J
26J
290
72J
9.7J
15J
21
490J
8J

Table 4-9 summarizes the results of the TAL inorganics detected in the fish and crab tissues at OU No. 2. Appendix G contains the data and frequency tables for these chemicals. The maximum concentration of the positively detected TAL inorganics in the Pumpkinseed tissue are as follows:

Constituent	Concentration (mg/kg)
Cadmium	0.06B
Calcium	19,500J
Magnesium	453
Potassium	2,720
Selenium	0.27J
Sodium	1,370J
Zinc	23.4

Pettiford Creek

The fish collected in Pettiford Creek were not submitted for tissue analysis.

4.5.2.2 Benthic Macroinvertebrate

Table 4-10 contains a systematic listing of the all the benthic macroinvertebrates collected in Wallace Creek, Bear Head Creek, and Pettiford Creek. Individuals were keyed out to their specific genus or species classifications, where possible. However, this level of precision was not achievable in all cases due to damaged or juvenile organisms. The following sections discuss the results of the benthic macroinvertebrate sampling in each creek.

Wallace Creek

Three phyla were represented in the collections from Wallace Creek: Arthropoda, Annelida and Nematoda. Nineteen taxa of benthic macroinvertebrates from these three phyla were collected from Wallace Creek. Of these 19 taxa, 90.5 percent of the species were arthropods, 8.5 percent of the species were annelids and one percent of the species were nematodes. The most abundant species in Wallace Creek was the chironomid <u>Tribelos jucundum</u> with 182 individuals (47 percent), followed by the amphipod <u>Gammarus fusciatus</u> (29 percent) with 113 individuals.

Biological data of each replicate are given in Appendix H. Table 4-11 summarizes the raw data by combining the replicates at each station. Overall species richness (i.e., number of species) and faunal densities (i.e., individuals per square meter) are shown on these tables. The percentages of each species at each station is provided in Table 4-12.

The number of species ranged from zero at Station 6-WC9A to 12 at Station 6-WC3A. The number of individuals ranged from zero at Station 6-WC9A to 200 at Station 6-WC3A. The species density values ranged from zero individuals/m² at Station 6-WC9A to 1,275 individuals/m² at Station 6-WC3A. Species diversity ranged from zero at Station 6-WC9A to 0.510 at Station 6-WC3A.

Macroinvertebrate Biotic Index values ranged from 6.46 at Station 6-WC3A to 9.80 at Station 6-WC11A (an MBI could not be calculated for Station 6-WC9A). Table 4-13 lists the BI and U.S. EPA tolerance to organic wastes and sensitivity to metals for the benthic macroinvertebrates collected in Wallace Creek, Bear Head Creek, and Pettiford Creek. See Table 4-14 for a summary of all the above statistics.

Figures 4-7 and 4-8 graphically display the numbers of taxa from the sampling stations at each replicate, and Figures 4-9 and 4-10 graphically display the total numbers of individuals at each sampling stations. Figures 4-11 and 4-12 graphically display the faunal densities from the sampling stations, and Figures 4-13 and 4-14 graphically display the species diversity values from the sampling stations. Figures 4-15 and 4-16 graphically display the MBI values from the sampling stations.

Bear Head Creek

Four phyla were represented in the collections from Bear Head Creek: Arthropoda, Annelida Platyhelminthes, and Mollusca. Thirty-nine taxa of benthic macroinvertebrates from these four phyla were collected from Bear Head Creek. Of these thirty-nine taxa, 20 percent of the species were arthropods, 44 percent of the species were annelids and 0.4 percent of the species were platyhelminthes and 35.6 percent were molluscs. The most abundant species in Bear Head Creek was the bivalve, <u>Pisidium casertanum</u> with 345 individuals (34 percent), followed by the oligochaete, <u>Isocheatides curvisetosus</u> with 261 individuals (26 percent).

Biological data of each replicate are given in Appendix H. Table 4-11 summarizes the raw data by combining the replicates at each station. Overall species richness (i.e., number of species) and faunal densities (i.e., individuals per square meter) are shown on these tables. The percentages of each species at each station is provided in Table 4-12.

The number of species ranged from one at Station 6-BH6A to 33 at Station 6-BH2A. The number of individuals ranged from four at Station 6-BH6A to 582 at Station 6-BH2A. The species density values ranged from 25 individuals/m² at Station 6-BH6A to 3,709 individuals/m² at Station 6-BH2A. Species diversity ranged from zero at Station 6-BH6A to 0.932 at Station 6-BH2A. Macroinvertebrate Biotic Index values ranged from 7.51 at Station 6-BH2A to 7.06 at Station 6-BH4A. See Table 4-14 for a summary of all the above statistics.

Figures 4-7 and 4-8 graphically display the numbers of species from the sampling stations at each replicate, and Figures 4-9 and 4-10 graphically display the total numbers of individuals at each sampling stations. Figures 4-11 and 4-12 graphically display the faunal densities from the sampling stations, and Figures 4-13 and 4-14 graphically display the species diversity values from the sampling stations. Figures 4-15 and 4-16 graphically display the MBI values from the sampling stations.

Pettiford Creek

Two phyla were represented in the collections from Pettiford Creek: Arthropoda and Annelida. Four taxa of benthic macroinvertebrates from these two phyla were collected from Pettiford Creek. Of these four taxa, 30 percent of the species were arthropods and 70 percent of the species were annelids. The most abundant species in Pettiford Creek was the oligochaete, <u>Limnodrilus hoffmeisteri</u> with 23 individuals (70 percent), followed by the chironomid <u>Tribelos jucundum</u> with 7 individuals (21 percent).

Biological data of each replicate are given in Appendix H. Table 4-11 summarizes the raw data by combining the replicates at each station. Overall species richness (i.e., number of species) and faunal densities (i.e., individuals per square meter) are shown on these tables. The percentages of each species at each station is provided in Table 4-12.

Four species were collected in Pettiford creek, consisting of 33 individuals. The species density was 210 individuals/m² and the species diversity was 0.372. The MBI value was 8.84. See Table 4-14 for a summary of all the above statistics.

Figures 4-7 and 4-8 graphically display the numbers of species from the sampling stations at each replicate, and Figures 4-9 and 4-10 graphically display the total numbers of individuals at each sampling stations. Figures 4-11 and 4-12 graphically display the faunal densities from the sampling stations, and Figures 4-13 and 4-14 graphically display the species diversity

values from the sampling stations. Figures 4-15 and 4-16 graphically display the MBI values from the sampling stations.

Similarity Index

The species community similarity between the stations were calculated for benthic macroinvertebrates collected in Wallace Creek, Bear Head Creek and Pettiford Creek (see Table 4-15). The S_J between the Wallace Creek stations ranged from 0 (between several stations) and 0.143 (between Station 6-WC3A and Station 6-WC6A), while the S_S ranged from 0 (between several stations) and 0.250 (between Station 6-WC3A and Station 6-WC6A). The S_J between the Bear Head Creek stations ranged from 0 (between several stations) and 0.306 (between Station 6-BH2A and Station 6-BH4A), while the S_S ranged from 0 (between several stations) and 0.468 (between Station 6-BH2A and Station 6-BH4A).

The S_J between Pettiford Creek and Wallace Creek ranged from 0 (between Station 6-WC9A and PC) and 0.545 (between Station 6-WC6A and PC), while the S_S ranged from 0 (between Station 6-WC9A and PC) and 0.375 (between Station 6-WC6A and PC). The S_J between Pettiford Creek and Bear Head Creek ranged from 0 (between Station 6-BH6A and PC) and 0.211 (between Station 6-BH4A and PC), while the Ss ranged from 0 (between Station 6-BH6A and PC) and 0.211 (between Station 6-BH4A and PC), while the Ss ranged from 0 (between Station 6-BH6A and PC) and 0.211 (between Station 6-BH4A and PC), while the Ss ranged from 0 (between Station 6-BH6A and PC) and 0.211 (between Station 6-BH4A and PC), while the Ss ranged from 0 (between Station 6-BH6A and PC) and 0.118 (between Station 6-BH4A and PC). The S_J between Wallace Creek and Bear Head Creek ranged from 0 (between several stations) and 0.333 (between Station 6-BH6A), while the S_S ranged from 0 (between several stations) and 0.500 (between Station 6-BH6A), while the S_S ranged from 0 (between several stations) and 0.500 (between Station 6-BH6A).

The results of these similarity index calculations showed that the stations were not very similar with regards to species composition. This was evident both in comparison of stations within a creek and between a creek. The highest similarity (0.5 to 0.6) was seen in comparison of stations between creeks, but the index calculated did not indicate very similar species compositions.

4.5.2.3 Terrestrial Fauna

Terrestrial fauna were not collected during this ecological investigation. Therefore, population and community ecological endpoints for terrestrial fauna could not be quantitatively evaluated in this report. The risks to terrestrial fauna discussed in the "Regional Ecology" section of this report will be quantitatively evaluated in this report by comparing estimated daily intakes to terrestrial reference values in Section 7.0 Risk Characterization/Integration.

5.0 CONTAMINANTS OF CONCERN

This section discusses the procedures used to evaluate the data for inclusion in the ERA. This section also includes a comparison of chemicals detected in the surface water and sediments to the applicable water quality and sediment quality criteria and a comparison of chemicals detected in the soil to plant and invertebrate toxicology data. Finally, a brief discussion of the physical/chemical characteristics of the COCs are included in this section.

5.1 Data Evaluation

This task uses a variety of information to select a list of COCs for each medium analyzed. The following rationale were used to determine and select the contaminants of concern per media for this site:

- Contaminants that were positively detected in at least one sample with no data qualifiers, and contaminants that indicate known identities but unknown concentrations
- Contaminants that were detected at elevated levels above the levels for the same contaminant detected in associated blanks
- Contaminants that were detected at elevated levels above naturally occurring levels of the same contaminant

Eliminating contaminants can be done through several procedures including: (1) historical information; (2) the detected concentration and contaminant's toxicity; (3) the contaminant's mobility and persistence; (4) exposure routes; and, (5) comparison to ARARs.

5.1.1 Contaminants of Concern - Surface Water

Surface water samples were collected at OU No. 2 from Wallace Creek, Bear Head Creek, and the ravine. The following sections discuss which chemicals were included in the ERA and the rationale for the chemicals that were not included in the ERA.

5.1.1.1 Wallace Creek

The following TCL organics detected in the surface water samples collected in Wallace Creek were not addressed in the ERA because they are common laboratory and/or decontamination contaminants: acetone and bis(2-ethylhexyl) phthalate. In addition, 2,4,6-trichlorophenol was not addressed in the ERA because it was only detected in one sample and it was not detected in any other sample at the site.

The following TAL inorganics detected in the surface water samples collected in Wallace Creek were not addressed in the ERA because of a lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: calcium, cobalt, magnesium, potassium, and sodium.

In summary, the following chemicals detected in the surface water samples collected in Wallace Creek are included in the ERA: 1,2-dichloroethane, tetrachloroethene, toluene, trichloroethene, vinyl chloride, aluminum, arsenic, barium, cadmium, chromium, copper, iron, lead, manganese, mercury, nickel, silver, vanadium, and zinc.

5.1.1.2 Bear Head Creek

The following TCL organics detected in the surface water samples collected in Bear Head Creek were not addressed in the ERA because they are common laboratory contaminants: bis(2-ethylhexyl) phthalate and diethyl phthalate. No other TCL organics were detected in the surface water in Bear Head Creek.

The following TAL inorganics detected in the surface water samples collected in Bear Head Creek were not addressed in the ERA because of a lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: calcium, magnesium, potassium, and sodium.

In summary, the following chemicals detected in the surface water in Bear Head Creek were addressed in the ERA: aluminum, barium, chromium, copper, iron, lead, manganese, mercury, nickel, silver, vanadium, and zinc.

5.1.1.3 Ravine

Acetone was the only TCL organic chemical detected in the surface water samples collected in ravine and was not addressed in the ERA because it is a common laboratory and decontamination contaminant.

The following TAL inorganics detected in the surface water samples collected in the ravine were not addressed in the ERA because of a lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: calcium, cobalt, magnesium, potassium, and sodium.

In summary, the following chemicals detected in surface water samples collected in the ravine were addressed in the ERA: aluminum, arsenic, barium, cadmium, chromium, copper, iron, lead, manganese, silver, vanadium, and zinc.

5.1.2 Contaminants of Concern - Sediments

Sediment samples were collected at OU No. 2 from Wallace Creek, Bear Head Creek, and the ravine. The following sections discuss which chemicals were included in the ERA, and the rationale for the chemicals that were not included in the ERA.

5.1.2.1 Wallace Creek

The following TCL organics detected in the sediment samples collected in Wallace Creek were not addressed in the ERA because they are common laboratory and/or decontamination contaminants: acetone, 2-butanone, methylene chloride, bis(2-ethylhexyl) phthalate, butyl benzyl phthalate, and diethyl phthalate.

The following TAL inorganics detected in the sediment samples collected in Wallace Creek were not addressed in the ERA because of a lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: calcium, cobalt, magnesium, potassium, and sodium.

In summary, the following chemicals detected in the sediment samples collected in Wallace Creek were addressed in the ERA: 1,2-dichloroethane, total xylenes, toluene, trichloroethene, carbon disulfide, dieldrin, 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, phenol, phenanthrene, flouranthene, pyrene, benzo(a)anthracene, chrysene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, aluminum, arsenic, barium, beryllium, chromium, copper, iron, lead, manganese, nickel, silver, vanadium, and zinc.

5.1.2.2 Bear Head Creek

The following TCL organics detected in the sediment samples collected in Bear Head Creek were not addressed in the ERA because they are common laboratory and/or decontamination contaminants: acetone, 2-butanone, and methylene chloride. In addition, alpha chlordane and 1,4-dichlorobenzene were not addressed in the ERA because they had low frequencies of detection and there is limited toxicological information for those chemicals.

The following TAL inorganics detected in the sediment samples collected in Bear Head Creek were not addressed in the ERA because of a lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: calcium, cobalt, magnesium, potassium, and sodium.

In summary, the following chemicals detected in the sediment samples collected in Bear Head Creek were addressed in the ERA: benzene, ethylbenzene, tetrachloroethene, trichloroethene, total xylenes, 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, PCB-1260, PAHs, aluminum, arsenic, barium, beryllium, cadmium, chromium, copper, iron, lead, manganese, selenium, vanadium, and zinc.

5.1.2.3 Ravine

The following TCL organics detected in the sediment samples collected in the ravine were not addressed in the ERA because they are common laboratory and/or decontamination contaminants: acetone, 2-butanone, bis(2-ethylhexyl) phthalate, and di-n-butyl phthalate. In addition, endrin aldehyde, carbazole, and dibenzofuran were not addressed in the ERA because they had low frequencies of detection and there is limited toxicological information for those chemicals.

The following TAL inorganics detected in the sediment samples collected in the ravine were not addressed in the ERA because of a lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: calcium, cobalt, magnesium, potassium, and sodium. In summary, the following chemicals detected in the sediment samples collected in the ravine were addressed in the ERA: dieldrin, 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, endrin, PCB-1260, PAHs, aluminum, arsenic, barium, beryllium, cadmium, chromium, copper, iron, lead, manganese, mercury, nickel, silver, vanadium, and zinc.

5.1.3 Contaminants of Concern - Surface Soils

The following sections discuss which chemicals were included in the ERA, and the rationale for the chemicals that were not included in the ERA.

5.1.3.1 Site 9

The following TCL organics detected in the surface soil samples were not addressed in the ERA because they are common laboratory and/or decontamination contaminants: acetone, bis(2-ethylhexyl) phthalate and toluene.

The following TAL inorganics detected in the surface soil were not addressed in the ERA because of a lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: aluminum, beryllium, calcium, cobalt, iron, magnesium, manganese, potassium and vanadium.

In summary, the following chemicals detected in the surface soil samples were addressed in the ERA: 4,4'-DDE, 4,4'-DDT, 1,1,1-trichloroethane, tetrachloroethene, pyrene, benzo(b)fluoranthene, barium, chromium, copper, lead, mercury, and zinc.

5.1.3.2 Site 6 (Lot 201)

Soil samples in this area were collected from three grid areas (i.e, grid locations 201A, 201B and 201C) in order to define the extent of contamination at the suspected PCB and pesticide storage areas.

The contaminants alpha and gamma chlordane were detected in only 1 of 96 samples, and PCB-1248 was detected in 1 of 87 samples therefore, these contaminants will not be retained as COCs for further evaluation.

The volatile contaminants acetone, methylene chloride, and 1,1,1-trichloroethane were not retained as COCs due to their infrequent detection and/or presence in field or laboratory blanks.

Several PAHs were detected throughout the site. The PAHs benzo(a)anthracene, benzo(k)fluoranthene, benzo(a)pyrene, and phenanthrene were detected in 1 of 17 samples, therefore they will not be retained as COCs for further evaluation. The presence of bis(2ethylhexyl)phthalate, di-n-butyl phthalate, and di-n-octyl phthalate are the result of blank contamination and therefore were not retained as COCs.

The following TAL inorganics detected in the surface soil were not addressed in the ERA because of lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: aluminum, beryllium, calcium, cobalt, iron, magnesium, manganese, potassium, selenium, sodium and vanadium.

In summary, the following chemicals detected in the surface soil samples were addressed in the ERA: 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, PCB-1260, chrysene, benzo(b)fluoranthene, 1,4-dichlorobenzene, fluoranthene, pyrene, arsenic, barium, cadmium, chromium, copper, lead, nickel, and zinc.

5.1.3.3 Site 6 (Lot 203)

Soil samples were collected from the area designated as Lot 203 Open Storage Area. Within this area, sampling grids (i.e. 203OSA, 203DDT, and 203PCB) were established to define areas of contamination.

Pesticides endosulfan II, alpha chlordane and gamma chlordane were detected infrequently and consequently were not retained as COCs. PCBs 1248 and 1254 were infrequently detected in this area and consequently were not retained as COCs.

The prevalence of TCL organics in this area does not warrant the retention of any of these as COCs for further evaluation. The infrequent detection and low concentrations of acetone and toluene detected in area soil samples indicate that these contaminants are blank related and not truly indicative of area-specific conditions. In addition, 1,1,1-trichloroethane was detected in 2 of 28 samples and does not warrant its retention as a COC.

Semivolatile contaminants benzo(a) anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, chrysene, 1,4-dichlorobenzene, fluoranthene, indeno(1,2,3-cd)pyrene, and pyrene were detected at frequencies that were greater than five percent. Therefore, these contaminants have been retained as COCs. Other semivolatiles (i.e., naphthalene, carbazole, and butyl benzyl phthalate) do not warrant consideration as COCs. These contaminants were either infrequently detected or are a result of blank contamination.

The following TAL inorganics detected in the surface soil were not addressed in the ERA because of lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: aluminum, antimony beryllium, calcium, cobalt, iron, magnesium, manganese, potassium, sodium and vanadium.

In summary, the following chemicals detected in the surface soil samples were addressed in the ERA: 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, dieldrin, endrin, PCB-1260, chrysene, benzo(b)fluoranthene, benzo(a)anthracene, benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, 1,4-dichlorobenzene, fluoranthene, pyrene, arsenic, barium, cadmium, chromium, copper, lead, mercury, nickel, and zinc.

5.1.3.4 Sites 6 (Wooded and Ravine Areas) and 82

The wooded and ravine areas consist of grid areas 201N (North), 201E (East), 201S (South) which bound Lot 201, and the wooded area north of Lot 203 bounded by Wallace Creek to the North, Piney Green Road to the East, and Holcomb Boulevard to the West. In addition, samples from the grid designated as 203OSA and the ravine were included as part of the wooded and ravine areas.

The pesticide alpha chlordane was detected in 1 of 83 samples in the surface soil, therefore, it was not retained as a COC.

The TCL organics acetone, bromomethane, chloromethane, 1,2-dichloroethene, trichloroethene, benzene, 1,1,2,2-tetrachloroethane, and toluene were not retained as COCs due to their infrequent occurrence in the soil and/or their presence in site or laboratory related blanks. Many of the semivolatile contaminants were not retained as COCs because they were either infrequently detected or are a result of blank contamination. The following TAL inorganics detected in the surface soil were not addressed in the ERA because of lack of available toxicological information or they were not expected to be ecologically significant at the detected concentrations: aluminum, antimony, beryllium, calcium, cobalt, iron, magnesium, manganese, potassium, selenium, silver, sodium, thallium and vanadium.

In summary, the following chemicals detected in the surface soil samples were addressed in the ERA: 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, dieldrin, endrin, PCB-1260, anthracene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, dibenz(a,h)anthracene, chrysene, indeno(1,2,3-cd)pyrene, 1,4-dichlorobenzene, fluoranthene, phenol, pyrene, arsenic, barium, cadmium, chromium, copper, lead, mercury, nickel, and zinc.

5.1.4 Contaminants of Concern - Fish and Crab Tissue

The following sections discuss the COCs in the fish and crabs tissues that were evaluated in the ERA.

5.1.4.1 Wallace Creek

For the tissue samples, endrin and endosulfan II were not addressed in the ERA because they were not detected in the sediment or surface water in Wallace Creek; therefore, they could not be attributed to contamination in Wallace Creek. Acetone, 2-butanone, methylene chloride, and dimethyl phthalate also were not evaluated in the ERA because they are common laboratory contaminants.

Selected TAL inorganics (calcium, magnesium, potassium and sodium) were not addressed in the ERA because they were not expected to be ecologically significant at the detected concentrations.

In summary, the following chemicals identified in the fish tissue will be addressed in the ERA: 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, toluene, PCB-1260, trichloroethene, phenol, benzene, silver, selenium and zinc.

5.1.4.2 Bear Head Creek

For the tissue samples, endrin, methoxychlor, and alpha chlordane were not addressed in the ERA because they were not detected in the sediment or surface water samples collected in Bear Head Creek; therefore, they could not be attributed to contamination in Bear Head Creek. Methylene chloride, acetone, 2-butanone, and dimethyl phthalate also were not evaluated in the ERA because they are common laboratory contaminants.

Selected TAL inorganics (calcium, magnesium, potassium and sodium) were not addressed in the ERA because they were not expected to be ecologically significant at the detected concentrations.

In summary, the following chemicals identified in the fish tissue will be addressed in the ERA: 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, toluene, PCB-1260, benzene, cadmium, selenium and zinc.

5.2 <u>Water Quality Criteria</u>

Tables 5-1 and 5-2, contain the North Carolina saltwater Water Quality Standards (WQS) and the Region IV saltwater Water Quality Screening Values (WQSV) for the COCs in Wallace Creek and Bear Head Creek. Table 5-3 contains the Freshwater WQS and WQSV for the COCs in the ravine. The COCs in the ravine are compared to the freshwater standards because the water in the ravine is not tidally influenced. The contaminants identified in the surface water were compared to these values to determine if they exceeded the published values. Tables 5-4, 5-5, and 5-6 lists the samples in which chemicals exceeded either the WQS or WQSV.

The water quality values for the following metals are water hardness dependent: cadmium, chromium III, copper, lead, nickel, silver, and zinc. In general, the higher the water hardness (in mg/l of CaCO₃) the higher the water quality value. A hardness concentration of 50 mg/l CaCO₃ was used to calculate these values.

5.2.1 Wallace Creek

Among the TAL inorganics, the WQS (5 ug/l) and the chronic (9.3 ug/l) WQSV for cadmium were exceeded in one sample (6-WC07-SW-312M), which had a cadmium concentration of 17.4J ug/l.

5-9

The WQS for copper (3 ug/l) was exceeded in five sample while the acute and chronic WQSV (2.9 ug/l) were exceeded in four samples, with the highest concentration of copper (209 ug/l) detected in sample 6-WC11-SW-312M.

The chronic WQSV for lead (5.6 ug/l) was exceeded in one sample (6-WC03-SW-312M), which had a lead concentration of 10.4 ug/l. Neither the WQS nor the acute WQSV for lead was exceeded in any of the samples. The WQS (0.025 ug/l) and chronic (0.025 ug/l) WQSV for mercury were exceeded in three samples with the highest concentration of mercury (0.52 ug/l) detected in samples 6-WC03-SW-312M and 6-WC11-SW-312M. The WQS (8.3 ug/l), the acute WQSV (789 ug/l), and the chronic WQSV (8.3 ug/l) for nickel were exceeded in four samples, with the highest concentration of nickel (1,380 ug/l) detected in sample 6-WC03-SW-312M. For silver, the WQS (0.1 ug/l), the acute (2.3 ug/l), and the chronic (0.23 ug/l) WQSVs were exceeded in one sample (6-WC05-SW-312M), which had a silver concentration of 2.6B ug/l. Finally, the WQS for zinc (86 ug/l) and the acute (95 ug/l) and chronic (86 ug/l) WQSVs were exceeded in two samples. The highest concentration of zinc was 111 ug/l detected in sample 6-WC03-SW-312M.

None of the TCL organic chemicals detected in the surface water samples collected from Wallace Creek exceeded the WQS or WQSV values.

Dissolved oxygen concentrations were less than the WQS (4.0 mg/l for an instantaneous reading) in 11 samples at seven stations. The pH value was not within the allowable WQS (6.8 to 8.5 for saltwaters) values in 20 samples, and the chronic WQSV (6.5 to 8.5) in 16 samples at ten stations.

The following chemicals detected in Wallace Creek surface water samples do not have N.C. WQS or Region IV screening values for them: aluminum, barium, iron, manganese, vanadium, 1,2-dichloroethane, tetrachloroethene, trichloroethane, and vinyl chloride. The potential impact to aquatic species from these chemicals in the surface water was evaluated using the results of acute and chronic tests obtained from the EPA Aquatic Information Retrieval (AQUIRE) database (AQUIRE, 1993). The maximum detected concentration of these chemicals in the surface water were below the adverse effects levels obtained from the database.

5.2.2 Bear Head Creek

Among the TAL inorganics, the WQS for copper (3 ug/l) and the acute (2.9 ug/l) and chronic (2.9 ug/l) WQSVs for copper were exceeded in sample 6-BH07-SW-312M (55.8 ug/l).

The chronic WQSV for lead (5.6 ug/l) was exceeded in two samples with the highest concentration of lead detected in sample 6-BH05-SW-06M (8.2 ug/l). The WQS and the chronic WQSV for mercury (0.025 ug/l) were exceeded in two samples with the highest concentration of mercury detected in sample 6-BH07-SW-312M (0.34B ug/l). This value did not exceed the acute WQSV.

The WQS (8.3 ug/l), the acute WQSV (75 ug/l), and the chronic WQSV (8.3 ug/l) for nickel were exceeded in sample 6-BH07-SW-312M (244 ug/l). Finally, the WQS (0.1 ug/l) and the chronic (0.23 ug/l) WQSV for silver were exceeded in two samples, while the acute WQSV (2.3 ug/l) was exceeded in one sample (6-BH07-SW-06B) which had a silver concentration of 3.6B ug/l.

None of the TCL organic chemicals detected in the surface water samples collected from Bear Head Creek exceeded the WQS or WQSV values.

Dissolved oxygen concentrations were less than the WQS (4.0 mg/l for an instantaneous reading) in two samples at two stations. The pH values were not within the allowable WSQ (6.8 to 8.5 for saltwaters) values in eight samples, and the chronic WQSV (6.5 to 8.5) in four samples at four stations.

The following chemicals detected in Bear Head Creek surface water samples do not have N.C. WQS or Region IV screening values for them: aluminum, barium, iron, manganese, and vanadium. The potential impact to aquatic species from these chemicals in the surface water was evaluated using the results of acute and chronic tests obtained from AQUIRE (AQUIRE, 1993). The maximum detected concentration of these chemicals in the surface water were below the adverse effects levels obtained from the database.

5.2.3 Ravine

The ravine is an intermittent tributary and usually there is water present only after a rain. Two of the proposed surface water samples could not be collected because there was not any water at the station.

Among the inorganic parameters, the chronic WQSV for aluminum (87 ug/l) was exceeded in six samples with the highest concentration of aluminum detected in sample 6-RV2-SW-06 (613 ug/l). The acute WQSV was not exceeded in any of the samples. The WQS for cadmium (2.0 ug/l) and the acute (1.79 ug/l) and chronic (0.66 ug/l) WQSVs were exceeded in two samples with the highest concentration of cadmium detected in sample 6-RV5-SW-06 (4.3JB).

The WQS for copper (7 ug/l) and the acute (9.22 ug/l) WQSV for copper were exceeded in four samples and the chronic WQSV (6.54 ug/l) was exceeded in two samples, with the highest concentration of copper detected in samples 6-RV2-SW-06 and 6-RV5-SW-06 (9JB ug/l). The WQS and the chronic WQSV for iron (1,000 ug/l) were exceeded in two samples with the highest concentration detected in sample 6-RV8-SW-06 (9,600 ug/l). The chronic WQSV for lead (1.32 ug/l) was exceeded in six samples, with the highest concentration of lead detected in sample 6-RV8-SW-06 (12.2 ug/l). None of the samples exceeded the WQS or the WQSV, 25 ug/l and 33.75 ug/l respectively, for lead.

The WQS for silver (0.06 ug/l) and the acute (1.23 ug/l) and chronic (0.012 ug/l) WQSVs for silver were exceeded in three samples with the highest concentration of silver detected in sample 6-RV6-SW-06 (67.6 ug/l). The WQS for zinc (50 ug/l) and the acute (65.04 ug/l) and chronic (58.91 ug/l) WQSVs for zinc were exceeded in six samples with the highest concentration of zinc detected in sample 6-RV6-SW-06 (495 ug/l).

None of the surface water samples collected from the ravine exceeded any established TCL organic parameter standards.

The following chemicals detected in the ravine surface water samples do not have N.C. WQS or Region IV screening values for them: barium, manganese, and vanadium. The potential impact to aquatic species from these chemicals in the surface water were evaluated using the results of acute and chronic tests obtained from AQUIRE (AQUIRE, 1993). The maximum detected concentration of these chemicals in the surface water were well below any of the adverse effects levels obtained from the database.

5.2.4 Pettiford Creek

Surface water samples were not collected from Pettiford creek for chemical analysis in accordance with the SAP (Baker, 1992). However, field water quality measurements were conducted during collection of the biological samples.

Dissolved oxygen concentrations were less than the WQS (4.0 mg/l for an instantaneous reading) in one sample. The pH was not measured in Pettiford Creek because the pH meter was not working.

5.3 <u>Sediment Screening Values</u>

Tables 5-7, 5-8, and 5-9 contain the Region IV sediment screening values (SQSV) for hazardous waste sites for the COCs at Site 6. The contaminants identified in the sediment were compared to these values to determine if they exceeded the published values. The NOAA ER-L values represent the lower screening values, while the NOAA ER-M Values represent the median screening values.

Tables 5-10, 5-11, and 5-12 lists the samples in which chemical concentrations exceeded the SQSV.

5.3.1 Wallace Creek

The ER-L for copper (70 mg/kg) was exceeded in two samples, while the ER-M (390 mg/kg) was exceeded in one sample with the highest concentration detected in sample 6-WC03-SD-06M (53,200 mg/kg). The ER-L for lead (35 mg/kg) was exceeded in nine samples, two of which exceeded the ER-M (110 mg/kg). The highest concentration of lead was detected in sample 6-WC03-SD-06M (314J mg/kg). The ER-L (1 mg/kg) and the ER-M (2.2 mg/kg) for silver were exceeded in sample 6-WC03-SD-06M, which had a silver concentration of 7.3 mg/kg. The ER-L for zinc (120 mg/kg) was exceeded in four samples, two of which exceeded the ER-M (270 mg/kg), with the highest concentration of zinc detected in sample 6-WC03-SD-06M (926 mg/kg).

Among TCL organics, the ER-L for 4,4'-DDE (2 ug/kg) was exceeded in fourteen samples, eleven of which exceeded the ER-M (15 ug/kg). The highest concentration of 4,4'-DDE was

detected in sample 6-WC09-SD-612M (83 ug/kg). The ER-L for 4,4'-DDD (2 ug/kg) was exceeded in fifteen samples, twelve of which exceeded the ER-M (20 ug/kg). The highest concentration of 4,4'-DDD was detected in sample 6-WC08-SD-612M (200J mg/kg). The ER-L (1 ug/kg) and the ER-M (7 ug/kg) for 4,4'-DDT were exceeded in three samples with the highest concentration detected in sample 6-WC08-SD-06M (1,200J ug/kg).

The ER-L for flouranthene (600 ug/kg) was exceeded in sample 6-WC08-SD-06B (760J ug/kg) and the ER-L (350 ug/kg) for pyrene was exceeded in sample 6-WC08-SD-06B (810J ug/kg). Neither the flouranthene nor the pyrene ER-MS, 3,600 ug/kg and 2,200 ug/kg, respectively, were exceeded in any samples. The ER-L for benzo(a)pyrene (400 ug/kg) was exceeded in three samples with the highest concentration detected in sample 6-WC05-SD-612B (1,600 ug/kg) and the ER-L for dieldrin (0.02 ug/kg) was exceeded in sample 6-WC01-SD-612D (4.8J ug/kg). Neither the benzo(a)pyrene nor the dieldrin ER-MS, 2,500 ug/lkg and 8 ug/kg respectively, were exceeded in any samples. Finally, the ER-L for PCB-1260 (50 ug/kg) was exceeded in twelve samples, six of which exceeded the median screening value (400 ug/kg). The highest concentration of PCB-1260 was detected in sample 6-WC08-SD-06M (2,100J mg/kg).

The following chemicals detected in Wallace Creek sediments do not have Region IV screening values for them: aluminum, barium, beryllium, iron, manganese, selenium, vanadium, 1,2dichloroethane, total xylenes, toluene, trichloroethene, carbon disulfide, benzo(b)fluoranthene, benzo(k)fluoranthene and phenol. There are either criteria or toxicity data for aquatic organisms exposed to these chemicals in water samples, however, there is limited, if any, data assessing the effects on aquatic organism exposed to these chemicals in sediment samples. Therefore, the effects of these chemicals on aquatic organisms cannot be determined. However, it should be noted that of these chemicals, only aluminum and iron exceeded state or federal water quality criteria for the surface water samples. None of these chemicals in the surface water for which criteria do not exist, exceeded the toxicity values obtained from AQUIRE. Finally, the toxicity of benzo(b)fluoranthene and benzo(k)fluoranthene are likely accounted for when the other PAHs are evaluated.

5.3.2 Bear Head Creek

Among the TAL inorganics, the ER-L for lead (35 mg/kg) was exceeded in five samples with the highest concentration of lead detected in sample 6-BH07-SD-06M (70.4J mg/kg). In no case was the ER-M exceeded. Among the TCL organics, the ER-L for 4,4'-DDE (2 ug/kg) was exceeded in eleven samples, nine of which exceeded the ER-M (15 ug/kg). The highest concentration of 4,4'-DDE was detected in sample 6-BH03-SD-06M (68 ug/kg). The ER-L for 4,4'-DDD (2 ug/kg) was exceeded in ten samples, seven of which exceeded the ER-M (20 ug/kg). The highest concentration of 4,4'-DDD was detected in sample 6-BH04-SD-612M (220J ug/kg). The ER-L for 4,4'-DDT (1 ug/kg) was exceeded in eight samples, six of which exceeded the median screening value (7 ug/kg). The highest concentration of 4,4'-DDT was detected in sample 6-BH04-SD-612M (38J ug/kg).

The ER-L for benzo(a)pyrene (400 ug/kg) was exceeded in two samples, with the highest concentration detected in sample 6-BH03-SD-612B (640 ug/kg). Finally, the ER-L for PCB-1260 (50 ug/kg) was exceeded in ten samples with the highest concentration of PCB-1260 detected in sample 6-BH04-SD-612M (370J ug/kg). The ER-M values for benzo(a)pyrene and PCB-1260, 2,500 ug/kg and 400 ug/kg respectively, were not exceeded in any samples.

The following chemicals detected in Bear Head Creek sediments do not have Region IV screening values for them: aluminum, barium, beryllium, iron, manganese, vanadium, benzene, ethylbenzene, tetrachloroethene, trichloroethene, total xylenes, benzo(b)fluoranthene, and indeno(1,2,3-cd)pyrene. There are either criteria or toxicity data for aquatic organisms exposed to these chemicals in water samples, however, there is limited, if any, data assessing the effects on aquatic organisms exposed to these chemicals in sediment samples. Therefore, the effects of these chemicals on aquatic organisms cannot be determined. However, it should be noted that of these chemicals, only aluminum and iron exceeded state or federal water quality criteria for the surface water samples. None of these chemicals in the surface water for which criteria do not exist, exceeded the toxicity values obtained from AQUIRE. Finally, the toxicity of benzo(b)fluoranthene, and indeno(1,2,3-cd)pyrene are likely accounted for when the other PAHs are evaluated.

5.3.3 Ravine

In addition to the ARAR comparison with sediment screening values, adverse ecological effects from contaminants in the ravine sediments will be compared to available toxicological data for ecological receptors exposed to contaminants in soils.

The ER-L for cadmium (5 mg/kg) was exceeded only in sample 6-RV1-SD-06 (5.9J mg/kg). The ER-L for lead (35 mg/kg) was exceeded in two samples with the highest concentration of lead

detected in sample 6-RV8-SD-06 (105J mg/kg). The ER-L for mercury (0.15 mg/kg) was exceeded in three samples with the highest concentration of mercury detected in sample 6-RV1-SD-06 (0.75 mg/kg). The ER-L for silver (1 mg/kg) was exceeded only in sample 6-RV8-SD-06 (1.2 mg/kg). In no cases were the ER-M values for cadmium, lead, mercury, or silver exceeded. Finally, the ER-L for zinc (120 mg/kg) was exceeded in four samples while the ER-M (270 mg/kg) for zinc was exceeded in one sample. The highest concentration of zinc was detected in sample 6-RV1-SD-06 (408 mg/kg).

Among the TCL organics, the ER-L (2 ug/kg) and the ER-M (15 ug/kg) for 4,4'-DDE were exceeded in six samples. The highest concentration of 4,4'-DDE was detected in sample 6-RV2-SD-06 (120J ug/kg). The ER-L for 4,4'-DDD (2 ug/kg) was exceeded in six samples, three of which exceeded the ER-M (20 ug/kg). The highest concentration of 4,4'-DDD was detected in sample 6-RV2-SD-06 (45J ug/kg). The ER-L (1 ug/kg) and the ER-M (7 ug/kg) for 4,4'-DDT were exceeded in eight samples with the highest concentration of 4,4'-DDT detected in sample 6-RV3-SD-06 (210J ug/kg).

The ER-L (0.02 ug/kg) and the ER-M (8 ug/kg) for dieldrin were exceeded in two samples with the higher concentration detected in sample 6-RV1-SD-07 (43J ug/kg). The ER-L for PCB-1260 (50 ug/kg) was exceeded in four samples with the the highest concentration of PCB-1260 detected in sample 6-RV1-SD-06 (360J ug/kg). The ER-L (0.02 ug/kg) for endrin was exceeded only in sample 6-RV1-SD-06 (5.1J ug/kg). The ER-M values for PCB-1260 and endrin were not exceeded.

Sample 6-RV2-SD-06 was the only sample in the ravine in which PAHs exceeded the ER-L values. The ER-L (225 ug/kg) and ER-M (1,380 ug/kg) for phenanthrene were exceeded in this sample (1,600 ug/kg) while the ER-L for flouranthene (600 ug/kg) also was exceeded in this sample (1,500J ug/kg). The ER-L for pyrene (350 ug/kg), benzo(a)anthracene (230 ug/kg), chrysene (400 ug/kg), dibenzo(a,h)anthracene (60 ug/kg), benzo(a)pyrene (400 ug/kg), acenapthene (150 ug/kg), fluorene (35 ug/kg), and anthracene (85 ug/kg) were all exceeded at this station due to the following sediment concentrations: pyrene (2,100 ug/kg), benzo(a)anthracene (1,100 ug/kg), chrysene (1,100 ug/kg), dibenzo(a,h)anthracene (83 ug/kg), and anthracene (480 ug/kg), and anthracene (480 ug/kg).

The following chemicals detected in the ravine sediments do not have Region IV screening values for them: aluminum, barium, beryllium, iron, manganese, vanadium,

5-16

benzo(b)fluoranthene, benzo(k)fluoranthene, and benzo(g,h,i)perylene and indeno(1,2,3-cd) pyrene. There are either criteria or toxicity data for aquatic organisms exposed to these chemicals in water samples, however, there is limited, if any, data assessing the effects on aquatic organism exposed to these chemicals in sediment samples. Therefore, the effects of these chemicals on aquatic organisms cannot be determined. However, it should be noted that of these chemicals, only aluminum and iron exceeded state or federal water quality criteria for the surface water samples. None of these chemicals in the surface water for which criteria do not exist, exceeded the toxicity values obtained from AQUIRE. Finally, the toxicity of benzo(b)fluoranthene, benzo(k)fluoranthene, and benzo(g,h,i)perylene are likely accounted for when the other PAHs are evaluated.

As discussed earlier in this section, the contaminants detected in the sediments will be compared to toxicological data associated with surface soils (See Section 5.4.4).

5.4 Surface Soil Quality

As discussed in the section above, there are no standards, criteria, or other screening values for assessing potential impacts to terrestrial ecological receptors from contaminants in soils. In addition, the amount of literature data evaluating adverse ecological effects on terrestrial species exposed to contaminants in surface soils is limited. The following paragraphs compare the concentrations of COCs detected in the surface soils to the published toxicity data. No information was found which evaluated the toxicological affects on plants and/or invertebrates inhabiting soils contaminated with TCL organics, therefore, the evaluation was limited to TAL inorganics.

5.4.1 Site 9

Toxicological effects on plants and/or invertebrates inhabiting soils contaminated by the following chemicals were obtained: barium, chromium, copper, lead, mercury, and zinc.

Barium concentrations in the surface soils ranged from 4.9JB to 8.9B mg/kg, which were below the 2,000 mg/kg that induced plant toxicity (Adriano, 1986). Chromium concentrations of 10 mg/kg in soil caused mortality in the earthworm species <u>Pheretima pesthuma</u> (Hopkin, 1989). Soil concentrations of chromium ranged from 1.7B to 5.1 mg/kg, which is below the 10 mg/kg toxicity level. Copper concentrations ranged from 0.93 JB to 2.8JB mg/kg, which are below the 50 mg/kg level that interfered with the reproduction activity of the earthworm

5-17

species <u>Allolobuphora caliginosa</u> (Hopkin, 1989). The concentrations of lead in the soil ranged from 4.1 to 25.7 mg/kg. The phytoxicity of lead was reported to be lower than that of copper, which would be greater than 50 mg/kg (Adriano, 1986). Mercury concentrations ranged from 0.02B to 0.03B mg/kg, which is less than the 0.79 mg/kg that caused toxicity to earthworms. (USDI, 1987). Finally, zinc concentrations ranged from 6.8 to 18.1 mg/kg, which are less than the 450 to 1,400 mg/kg that caused plant toxicity (Adriano, 1986).

5.4.2 Site 6 (Lot 201)

Toxicological effects on plants and/or invertebrates inhabiting soil contaminated by the following chemicals was obtained: arsenic, barium, cadmium, chromium, copper, lead, nickel and zinc.

Arsenic concentrations ranged from 0.91B to 9.7J mg/kg which were below the 25 mg/kg that depressed crop yields (USDI, 1988). Barium concentrations ranged from 3.5 JB to 16.5 B mg/kg which were below the 2,000 mg/kg that induced plant toxicity (Adriano, 1986). Cadmium concentrations ranged from 0.51 JB to 1.5 J mg/kg which were higher than the 0.5 mg/kg level that caused low toxicity in the earthworm species <u>Lumbricus rubellus</u> (Hopkin, 1989).

Soil concentrations of chromium ranged from 3.5 to 21.6 mg/kg, some of which exceeded the 10 mg/kg that caused mortality in the earthworm species <u>Pheretima pesthuma</u> (Hopkin, 1989). Copper concentrations ranged from 0.75JB to 27.81 mg/kg which were below the 50 mg/kg level that interfered with the reproduction activity of the earthworm species <u>Allolobuphora caliginosa</u> (Hopkin, 1989). The phytoxicity of lead is low compared with other trace elements such as cadmium, copper, nickel, and arsenic (Adriano, 1986). The concentrations of lead ranged from 1J to 78 mg/kg which cannot be evaluated because a specific toxicity level for lead was not found. Nickel concentrations ranged from 3.7B to 6.4JB mg/kg which were less than the 17 mg/kg that caused low toxicity to the earthworm species <u>Lumbricus rubellus</u> (Hopkin, 1989). Finally, zinc concentrations ranged from 4.6 to 135J mg/kg which were less than the 450 mg/kg causing plant toxicity (Adriano, 1986).

5.4.3 Site 6 (Lot 203)

Toxicological effects on plants and/or invertebrates inhabiting soil contaminated by the following chemicals was obtained: arsenic, barium, cadmium, chromium, copper, lead, mercury, nickel, and zinc.

Arsenic concentrations ranged from 0.39B to 4.9 mg/kg which were below the 25 mg/kg that depressed crop yields (USDI, 1988). Barium concentrations ranged from 2.7JB to 47.8 mg/kg which were below the 2,000 mg/kg that induced plant toxicity (Adriano, 1986). Cadmium concentrations ranged from 0.48 to 9.3 mg/kg which were higher than the 0.5 mg/kg level that caused low toxicity in the earthworm species Lumbricus rubellus (Hopkin, 1989).

Soil concentrations of chromium ranged from 1.1 to 25.2 mg/kg, some of which exceeded the 10 mg/kg that caused mortality in the earthworm species <u>Pheretima pesthuma</u> (Hopkin, 1989). Copper concentrations ranged from 1JB to 75 mg/kg, some of which exceeded the 50 mg/kg level that interfered with the reproduction activity of the earthworm species <u>Allolobuphora caliginosa</u> (Hopkin, 1989). The phytoxicity of lead is low compared with other trace elements such as cadmium, copper, nickel, and arsenic (Adriano, 1986). The concentrations of lead ranged from 4.1 to 4,010J mg/kg which cannot be evaluated because a specific toxicity level for lead was not found. Mercury concentrations ranged from 0.03B to 1.1 mg/kg, some of which exceeded the 0.79 mg/kg level that was toxic to the earthworm species <u>Octochaetus pattoni</u> (USDI, 1987). Nickel concentrations ranged from 1.8JB to 13.2 mg/kg which were less than the 17 mg/kg that caused low toxicity to the earthworm species <u>Lumbricus rubellus</u> (Hopkin, 1989). Finally, zinc concentrations ranged from 1.1B to 604 mg/kg some of which exceeded the 450 mg/kg causing plant toxicity (Adriano, 1986).

5.4.4 Sites 6 (Wooded and Ravine Areas) and 82

Toxicological effects on plants and/or invertebrates inhabiting soil contaminated by the following chemicals was obtained: arsenic, barium, cadmium, chromium, copper, lead, mercury, nickel and zinc.

Arsenic concentrations ranged from 0.49B to 26.3 mg/kg, most of which were below the 25 mg/kg that depressed crop yields (USDI, 1988). Barium concentrations ranged from 1.1JB to 1,410 mg/kg which were below the 2,000 mg/kg that induced plant toxicity (Adriano, 1986). Cadmium concentrations ranged from 0.4JB to 51.9 mg/kg, most of which exceeded the 0.5

mg/kg level that caused low toxicity in the earthworm species <u>Lumbricus</u> rubellus (Hopkin, 1989).

Soil concentrations of chromium ranged from 0.72B to 54.6 mg/kg, some of which exceed the 10 mg/kg that caused mortality in the earthworm species <u>Pheretima pesthuma</u> (Hopkin, 1989). Copper concentrations ranged from 0.39JB to 348 mg/kg, some of which were below the 50 mg/kg level that interfered with the reproduction activity of the earthworm species <u>Allolobuphora caliginosa</u> (Hopkin, 1989). The phytoxicity of lead is low compared with other trace elements such as cadmium, copper, nickel, and arsenic (Adriano, 1986). The concentrations of lead ranged from 2 to 1,710 mg/kg which cannot be evaluated because a specific toxicity level for lead was not found. Mercury concentrations ranged from 0.02B to 3.9 mg/kg, some of which exceeded the 0.79 mg/kg level that was toxic to the earthworm <u>Octochaetus pattoni</u> (USDI, 1987). Nickel concentrations ranged from 1.7B to 79.4 mg/kg, some of which exceeded the 17 mg/kg that caused low toxicity to the earthworm species <u>Lumbricus rubellus</u> (Hopkin, 1989). Finally, zinc concentrations ranged from 1.6 to 16,600 mg/kg, some of which exceeded the 450 mg/kg causing plant toxicity (Adriano, 1986).

5.5 <u>Physical/Chemical Characteristics</u>

Table 5-13 contains values for bioconcentration factors, water solubility, organic carbon partition coefficient, and vapor pressure for the contaminants identified in the sediments, surface water and surface soil samples. Information from this table was used in the risk characterization to assess the fate and transport of the constituents and the potential risks to the environmental receptors. The following paragraphs discuss the significance of each parameter included in the table.

Bioconcentration factors (BCF) measure the tendency for a chemical to partition from the water column or sediment and concentrate in aquatic organisms. This factor is important for ecological receptors because chemicals with high bioconcentration factors could accumulate in lower-order species and subsequently accumulate to toxic levels in higher-order species that consume the lower-order species. Bioconcentration factors among the metals range from 19 for beryllium to 350,000 for manganese, and 1.17 for vinyl chloride to 100,000 for PCB-1260 among the organics. The pesticides have the highest potential to concentrate in the fish or crab tissue. Published BCF data were not available for some of the COCs at OU No. 2.

Water solubility is important in the ecological environment because it measures the tendency for a chemical to remain dissolved in the water column, partition to soil or sediment, or bioconcentrate in aquatic organisms. Chemicals with high water solubilities tend to be more bioavailable to aquatic organisms. However, they will not significantly bioconcentrate in the organisms. On the other hand, chemicals with a low water solubility will remain bound to the sediment and soils but may bioconcentrate in organisms to a significant degree. Water solubility for metals is not applicable because they are practically insoluble in water. The water solubility of the organics ranged from less than 0.01 mg/l for the PAHs to 83,000 mg/l for phenol.

The organic carbon partition coefficient (Koc) measures the tendency for a chemical to partition between soil or sediment particles containing organic carbon and water. This coefficient is important in the ecological environment because it determines how strongly an organic chemical will be bound to the organics in the sediments. The Koc is highest for the pesticides ($4 \ge 10^6$ ml/g) and lowest for phenol (14.2 ml/g). Koc values are not applicable for metals.

The vapor pressure measures the tendency for a chemical to partition into air. This parameter is important for the ecological environment because it can be used to determine the concentrations of the constituents in air. The vapor pressure is highest for vinyl chloride (3,000 mm Hg). Other contaminants with significant vapor pressure values include benzene (95 mm Hg), carbon disulfide (360 mm Hg), and 1,2-dichloroethane (79 mm Hg). The vapor pressure for the most other contaminants of concern are low or negligible.

6.0 ECOLOGICAL EXPOSURE CHARACTERIZATION

This section of the ERA addresses each exposure pathway via surface water, sediment, air, soil, and groundwater. To determine if ecological exposure via these pathways may occur in the absence of remedial actions, an analysis was conducted including the identification and characterization of the exposure pathways. The following four elements were examined to determine if a complete exposure pathway was present:

- a source and mechanism of chemical release
- an environmental transport medium
- a feasible receptor exposure route
- a receptor exposure point

6.1 <u>Potential Exposure Scenarios</u>

This section discusses the potential exposure scenarios at OU No. 2 including surface water, sediments, air, soil, and groundwater.

6.1.1 Surface Water Exposure Pathway

Potential release sources to be considered in evaluating the surface water pathway are contaminated surface soils and groundwater. The release mechanisms to be considered are groundwater seepage and surface runoff. The potential routes to be considered for ecological exposure to the contaminated surface waters are ingestion and dermal contact. Potential exposure points for ecological receptors include species living in, or coming in contact with, the surface water onsite or offsite and downgradient relative to tidal influence.

Potential receptors that may be exposed to contaminants in surface waters include fish, crabs, benthic macroinvertebrates, birds, and other aquatic and terrestrial life.

Fish and crabs are exposed to contaminants in the surface water by ingesting water while feeding and by direct contact. Overall, fish and crabs have a high exposure to contaminants in the surface water. Potential adverse effects on fish and crabs from contaminants in the surface water were quantitatively evaluated by direct comparisons of contaminant concentrations in the surface water to published water quality standards, by the use of species diversity and similarity indices, and by fish and crab tissue analysis.

6-1

Benthic macroinvertebrates may swim through the water column and/or may attach themselves to substrates in the surface water. These species have a high potential exposure to contaminants in the surface water because they are in constant contact with the water and often they ingest water while feeding. Potential adverse effects on benthic macroinvertebrates from contaminants in the surface water were quantitatively evaluated by direct comparisons of contaminant concentrations in the surface water to published water quality standards and by use of species diversity index, similarity indices, and biotic indices.

Terrestrial faunal receptors potentially are exposed to contaminants in the surface water through ingestion and dermal contact. The magnitude of the exposure depends on their feeding habits and the amount of time they reside in the contaminated waters. In addition, terrestrial species may ingest organisms (e.g., fish, insects, plants) that have bioconcentrated contaminates from the surface water. Risk to terrestrial vertebrate ecological receptors was quantitatively evaluated by comparing chronic daily intake estimates to terrestrial reference values.

Finally, other aquatic organisms (e.g., zooplankton, microinvertebrates) and aquatic plants are potentially exposed to contaminants in the surface water. These aquatic organisms are a primary food source for the benthic macroinvertebrates, crabs, and fish examined in this ERA. In addition aquatic flora add oxygen to the water through photosynthesis, add nutrients to the sediments when degraded, provide cover for small aquatic organisms and are ingested by aquatic and terrestrial fauna. These potential receptors were qualitatively evaluated in the ERA.

6.1.2 Sediment Exposure Pathway

The potential release source to be considered in evaluating the sediment pathway are contaminated surface soils and groundwater. The release mechanisms to be considered are groundwater seepage and surface runoff. The potential routes to be considered for ecological exposure to the contaminated sediments are ingestion and dermal contact. Potential exposure points for ecological receptors include species living in, or coming in contact with, the sediments onsite or offsite and downgradient relative to tidal influence.

Potential receptors that may be exposed to contaminated sediments include benthic macroinvertebrates, bottom feeding fish, aquatic vegetation and other aquatic life.

6-2

Fish (especially bottom feeders) and crabs are exposed to contaminants in the sediments by ingesting sediments while feeding on benthic macroinvertebrates and/or organic detritus or by direct contact with the sediments. In addition, fish and crabs may ingest benthic macroinvertebrates that have bioconcentrated chemicals from the sediments. Overall, fish and crabs have a high potential exposure to contaminants in the sediments. Potential adverse effects on fish and crabs from contaminants in the sediments were quantitatively evaluated by direct comparisons of contaminant concentrations in the sediments to Region IV sediment screening values, by the species diversity index, and by fish and crab tissue analysis.

Benthic macroinvertebrates reside on the bottom of the water bodies either on or in the sediments. They are exposed to contaminants in sediments by ingesting sediments while feeding or burrowing and by direct contact. Therefore, they have a very high potential exposure to the contaminants. Potential adverse effects of benthic macroinvertebrates from contaminants in the sediments were quantitatively evaluated by direct comparisons of contaminant concentrations in the sediments to Region IV sediment screening values and by the use of the species diversity index and similarity indices.

Terrestrial faunal receptors potentially are exposed to contaminants in the sediments through ingestion and dermal contact. The magnitude of the exposure depends on their feeding habits and the amount of time they reside in the contaminated sediments. In addition, terrestrial species may ingest organisms (e.g., fish, insects, plants) that have bioconcentrated contaminants from the sediments. Risk to terrestrial ecological receptors was limited to a qualitative evaluation.

Finally, other aquatic organisms (e.g., zooplankton, microinvertebrates) and aquatic plants are potentially exposed to contaminants in the sediments. These aquatic organisms are a primary food source for the benthic macroinvertebrates, crabs, and fish examined in this ERA. In addition aquatic flora add oxygen to the water through photosynthesis, add nutrients to the sediments when degraded, provide cover for small aquatic organisms and are ingested aquatic and terrestrial fauna. These potential receptors were qualitatively evaluated in the ERA.

6.1.3 Air Exposure Pathway

There are two potential release mechanisms to be considered in evaluating the atmospheric pathway: release of contaminated particulates and volatilization from surface soil,

groundwater and surface water. The potential exposure points for receptors are areas on or adjacent to the site.

No data has been collected to document exposure to receptors via the air pathway. However, based on the low concentrations of VOCs detected in the soils, sediments, and surface water, the air concentration of these contaminants is not expected to cause a risk to the terrestrial ecology. Therefore, this pathway was not evaluated as part of the ERA.

6.1.4 Soil Exposure Pathway

Potential release sources to be considered in evaluating the soil pathway are surface or buried wastes and contaminated soil. The release mechanisms to be considered are fugitive dust, leaching, tracking, and surface runoff. The transport medium is the soil. The potential routes to be considered for ecological exposure to the contaminated soils are ingestion and dermal contact. Potential exposure points for ecological receptors include species living in, or coming in contact with, the soils. Terrestrial fauna receptors potentially are exposed to contaminants in the surface soils through incidental ingestion of surface soils and bioaccumulation/bioconcentration in prey. The magnitude of the exposure depends on their breeding habits and the amount of time they reside on the contaminated soils. In addition, terrestrial species may ingest other terrestrial species that have bioconcentrated or bioaccumulated contaminants from the surface soils. Risks to terrestrial vertebrate ecological receptors was quantitatively evaluated by comparing chronic daily intake estimates to terrestrial reference values.

6.1.5 Groundwater Exposure Pathway

The potential release source to be considered in evaluating the groundwater pathway are contaminated soils. The release mechanism to be considered is leaching. The routes to be considered for ecological exposure to the contaminated groundwater are ingestion and dermal contact. Groundwater discharge to area surface waters may represent a pathway for contaminant migration. Groundwater to surface water exposure will be evaluated in the surface water section of the ERA.

7.0 RISK CHARACTERIZATION / INTEGRATION

This section discusses the results of the sampling conducted during the remedial investigations at OU No. 2 and evaluates the potential impact on the ecological integrity of Wallace Creek, Bear Head Creek, and the ravine from contaminants identified at OU No. 2.

7.1 <u>Water Quality</u>

The concentrations of contaminants in the surface water were compared to applicable State and Federal water quality standards (see Tables 5-1, 5-2 and 5-3). Water quality criteria values are set to be protective of the aquatic environment and any exceedences of these criteria indicate a potentially hazardous environment for the aquatic organisms inhabiting the water body. However, because the surface water sampling program was a "snapshot" in time, it represents only one set of data points on a potential continuum of possible values. Variations in regional and local meteorological conditions can result in variations in stream flow and tidal influence as well as groundwater discharge that may significantly change the observed results either higher or lower. Therefore, based on the information collected and evaluated in the following sections, the exceedences noted would result in potential chronic toxicity if the data points were representative of long-term conditions.

7.1.1 Wallace Creek

Surface water concentrations of cadmium, copper, lead, mercury, nickel, silver, and zinc exceeded the North Carolina Water Quality Standards (WQS) and/or U.S. EPA Region IV acute or chronic Water Quality Screening Values (WQSV) in some of the samples.

Cadmium exceeded the WQS and the acute and chronic WQSVs in one sample, and copper exceeded the WQS in five samples and the acute and chronic WQSVs in six samples. Lead exceeded the chronic WQSV in one sample, and mercury exceeded the WQS and chronic WQSV in three samples. Nickel exceeded all three values in four samples. Finally silver and zinc exceeded the WQS and the acute and chronic WQSV in one and two samples, respectively.

Mercury, nickel and zinc exceeded water quality values in both upstream and downstream samples, therefore it is unlikely that those materials are site related. Lead exceeded the criteria only in one upstream sample and was not detected in samples downstream of the site. Also, cadmium and silver were only detected in four or less samples at the site, therefore no trend could be determined. Overall, there does not appear to be any association of TAL inorganics with contaminants from OU No.2.

The ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV was calculated for each COC. A ratio greater than unity indicated a potential for adverse effects to aquatic life. The following lists the ratios that were greater than unity:

	Chronic	
Chemical	<u>WQSV</u>	<u>Ratio</u>
Copper	2.9	4.9
Mercury	0.025	5.6
Nickel	8.3	5.4
Silver	0.23	14.2*

* Maximum value used

None of the chemicals for which WQS or WQSV were not established exceeded toxicological data available from the literature. Therefore, no adverse effects to the ecological receptors from these metals is expected.

Dissolved oxygen concentrations exceeded (were less than) the WQS in eleven samples. The pH values were not within the allowable WQS values in twenty samples and the chronic WQSV in sixteen samples (there is no acute WQSV for pH). The low dissolved oxygen values may be the cause of the absence and/or low number of benthic macroinvertebrates collected from two of the stations on Wallace Creek. The low dissolved oxygen concentrations and pH values are probably associated with natural conditions, rather than being site related.

Several of the COCs exceeded either the State and/or Federal water quality values and had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in Wallace Creek to be adversely affected by chronic toxicity from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represents long-term conditions.

7.1.2 Bear Head Creek

Surface water concentrations of copper, lead, mercury, nickel and silver exceeded the WQS and/or acute or chronic WQSV in some of the samples.

Copper exceeded all three values in one sample. Lead exceeded the chronic WQSV in two samples. Mercury exceeded the WQS and the chronic WQSV in two samples, and nickel exceeded all three values in one sample. Finally, silver exceeded the WQS and the chronic WQSV in two samples, and the acute WQSV in one sample.

The ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV was calculated for each COC. A ratio greater than unity indicated a potential for adverse effects to aquatic life. The following list the ratios that were greater than unity:

Chemical	<u>Ratio</u>
Copper	2.4
Mercury	2.0
Nickel	2.2
Silver	18.3*

* Maximum value used

None of the chemicals for which WQS or WQSV were not established exceeded toxicological data available from the literature. Therefore, no adverse effects to the ecological receptors from these chemicals is expected.

Lead exceeded the water quality values in both the upstream and downstream samples, therefore it is unlikely that these metals are site related. Copper, nickel and silver exceeded the criteria in the furthest downstream samples only. It is unlikely that these metals are site related because copper and nickel were not detected in any other samples, and the only other sample that silver was detected in was upstream of the site. Mercury exceeded the water quality values immediately downstream from the sites and in the furthest downstream sample. However, mercury was not detected in the samples collected adjacent to the sites, or in the bank samples at the stations where mercury was detected onsite.

Dissolved oxygen concentrations exceeded (were less than) the WQS in two samples. The pH values were not within the allowable WSQ values in eight samples, and not within the

allowable chronic WQSV in four samples. The low dissolved oxygen concentrations and pH values are probably associated with natural conditions, rather than being site related.

Several of the COCs exceeded either the State and/or Federal water quality values and had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in Bear Head Creek to be adversely affected by chronic toxicity from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represents long-term conditions.

7.1.3 Ravine

Surface water concentrations of aluminum, cadmium, copper, iron, lead, silver and zinc exceeded the WQS and/or acute or chronic WQSV in some of the samples.

Aluminum exceeded the chronic WQSV in six samples and cadmium exceeded the WQS and the acute and chronic WQSV in two samples. Copper and iron exceeded the WQS and chronic WQSV in four and two samples, respectively. Lead exceeded the chronic WQSV in six samples. Finally, silver and zinc exceeded the WQS and the acute and chronic WQSV in three and six samples, respectively.

The ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV was calculated for each COC. A ratio greater than unity indicated a potential for adverse effects to aquatic life. The following list portrays the ratios that were greater than unity:

<u>Ratio</u>
7.0*
6.1
1.4*
12.3
8.3
5,063.3
8.4*

* Maximum value used

None of the chemicals for which WQS or WQSV were not established exceeded toxicological data available from the literature. Therefore, no adverse effects to the ecological receptors from these chemicals is expected.

Field water quality measurements were not conducted in the ravine because of the intermittent nature of the water.

Several of the COCs exceeded either the State and/or Federal water quality values and had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in the ravine to be adversely affected by chronic toxicity from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represent long-term conditions. The ravine originates in Site 6 and extends into Site 82. Therefore, any contamination detected in the ravine may be related to Sites 6 and 82.

7.1.4 Pettiford Creek

Surface water samples were not collected from Pettiford Creek for chemical analysis. However, field water quality measurements were conducted during the fish and benthic macroinverterbate sampling events.

Dissolved oxygen concentrations were less than the WQS in one sample. The pH was not measured in Pettiford Creek because the pH meter was not working. The low dissolved oxygen concentrations were probably associated with natural conditions.

7.2 Sediment Quality

The concentrations of contaminants in the sediments were compared to the Region IV lower 10 percentile (ER-L) and median percentile (ER-M) sediment screening values (SQSV) (see Tables 5-4, 5-5, and 5-6). Because the screening values are set to be protective of the aquatic environment, any exceedences of these values indicate a potentially toxic environment for the aquatic organisms inhabiting the water body.

7.2.1 Wallace Creek

Sediment concentrations of copper, lead, silver, zinc, 4,4'-DDE, 4',4-DDD, 4',4-DDT, dieldrin, PCB-1260, benzo(a)pyrene, fluoranthene, and pyrene exceeded the ER-L and/or ER-M in some of the samples.

Copper exceeded the ER-L in two samples and the ER-M in one sample, while lead exceeded the ER-L in nine samples and the ER-M in two samples. Silver exceeded the ER-L and ER-M in one sample. Finally, zinc exceeded the ER-L in four samples and the ER-M in two samples. 4,4'-DDE exceeded the ER-L and ER-M in 14 and 11 samples, respectively. 4,4'-DDD exceeded the ER-L and ER-M in 15 and 12 samples, respectively. 4,4'-DDT and dieldrin exceeded the ER-L and ER-M in three samples, and dieldrin exceeded the ER-L in one sample. PCB-1260 exceeded the ER-L in 12 samples and the ER-M in six samples. Finally, benzo(a)pyrene, fluoranthene, and pyrene exceeded the ER-L in three, one, and two samples, respectively.

The ratio of the upper confidence limit and the ER-L was calculated for each COC. A ratio greater than unity indicated a possibility for adverse effects to aquatic life, and EPA recommends conducting toxicity tests as a follow-up. The following list the ratios that were greater than unity:

Chemical	<u>Ratio</u>
Lead	1.0
Silver	1.6
4,4'-DDE	9.8
4,4'-DDD	15.5
4,4'-DDT	22.9
Dieldrin	240.0*
PCB-1260	6.1
Benzo (a) anthracene	1.0*
Benzo (a) pyrene	1.5
Pyrene	1.3

* Maximum value used

Literature data were not identified for determining the effects on aquatic life from contaminants for which there was not a screening value. It should be noted that of these contaminants, only aluminum and iron exceeded state or federal water quality criteria for the surface water samples. None of these contaminants for which criteria do not exist exceeded the toxicity values obtained from AQUIRE.

The exceedences of the inorganic chemicals occurred in both the upstream and downstream samples, therefore, these exceedences do not appear to be site related. Dieldrin was only detected in the furthest-most upstream station, therefore it is not site related. Except for one sample, 4,4'-DDE, 4,4'-DDD, 4,4'-DDT only exceeded the SQSV in the samples collected adjacent to, and downstream of OU No. 2, therefore, these contaminants might be attributable to runoff from the site. The PAHs primarily were detected adjacent to Piney Green Road and Holcomb Boulevard. Therefore, they are probably due to the automobile traffic on those roads. Finally, PCB-1260 exceeded the SQSV in the 0 to 6-inch sediment samples collected adjacent to and downstream of OU No. 2. PCB-1260 was detected in just two samples upstream of OU No. 2, therefore, PCB-1260 potentially may be associated with contamination at OU No.2.

Several of the COCs exceeded the ER-L and/or ER-M and had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in Wallace Creek to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

7.2.2 Bear Head Creek

Sediment concentrations of lead, 4,4'-DDE, 4,4'-DDD, 4,4'-DDT, PCB-1260 and benzo(a)pyrene exceeded the ER-L and/or ER-M in some of the samples.

Lead exceeded the ER-L in five samples. 4,4'-DDE, 4,4'-DDD, and 4,4'-DDT exceeded the ER-L in 11, 10, and eight samples, respectively, and the ER-M in nine, seven, and six samples respectively. PCB-1260 exceeded the ER-L in 10 samples and benzo(a)pyrene exceeded the ER-L in one sample.

The ratio of the upper confidence limit and the ER-L was calculated for each COC. A ratio greater than unity indicated a possibility for adverse effects to aquatic life, and EPA recommends conducting toxicity tests as a follow-up. The following list portrays the ratios that were greater than unity:

<u>Chemical</u>	<u>Ratio</u>
4,4'-DDE	17.3

4,4'-DDD	14.7
4,4'-DDT	13.5
PCB-1260	3.0
Benzo(a)pyrene	1.3
Pyrene	1.5

The exceedences of lead occurred in both the upstream and downstream samples, therefore, these exceedences do not appear to be site related. Most of the SQSV exceedences for 4,4'-DDE, 4,4'-DDD, 4,4'-DDT were in samples collected from the three stations adjacent to, and immediately downstream of OU No.2. Therefore, these contaminants might be attributable to runoff from the site. Benzo(a)pyrene only exceeded the SQSV at one station, which was located upstream of OU No.2 and adjacent to Piney Green Road. Therefore, benzo(a)pyrene is probably due to the automobile traffic on this road. Finally, PCB-1260 exceeded the SQSV in samples collected from the stations upstream, adjacent to, and downstream of OU No.2. Therefore, PCBs are likely related to OU No.2.

Several of the COCs exceeded the ER-L and/or ER-M and had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in Bear Head Creek to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

7.2.3 Ravine

Sediment concentrations of cadmium, lead, mercury, silver, zinc, 4,4'-DDE, 4',4-DDD, 4',4-DDT, dieldrin, endrin, PCB-1260, and several of the PAHs exceeded the ER-L and/or ER-M. The ravine is located adjacent to Site 6 and receives runoff from this site. Therefore, any contamination detected in the ravine would be site related or due to natural concentrations (especially for many of the metals).

Cadmium and lead exceeded the ER-L in one and two samples, respectively, and mercury and silver exceeded the ER-L in three and one sample, respectively. Zinc exceeded the ER-L in four samples and the ER-M in one sample. 4,4'-DDE, 4,4'-DDD, 4,4'-DDT and dieldrin exceeded the ER-L in six, six, eight and two samples, respectively, and the ER-M in six, three, eight, and two samples, respectively. Endrin exceeded the ER-L one sample. PCB-1260 exceeded the ER-L in four samples. Finally, ten PAHs exceeded the ER-L in one sample, while one PAH (phenanthrene) exceeded the ER-M in one sample.

The ratio of the upper confidence limit and the ER-L was calculated for each COC. A ratio greater than unity indicated a possibility for adverse effects to aquatic life, and EPA recommends conducting toxicity tests as a follow-up. The following list portrays the ratios that were greater than unity:

<u>Chemical</u>	Ratio
Lead	1.1
Mercury	2.1
Silver	1.1
Zinc	1.6
4,4'-DDE	41.0
4,4'-DDD	13.6
4,4'-DDT	187.4
Dieldrin	655.0
Endrin	255.0*
PCB-1260	3.0
Acenaphthene	1.5*
Anthracene	3.3
Benzo(a)anthracene	2.2
Benzo(a)pyrene	1.0
Chrysene	1.1
Dibenz(a,h)anthracene	1.4*
Phenanthrene	1.9
Pyrene	1.5

* Maximum value used

Several of the COCs exceeded the ER-L and/or ER-M and had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in the ravine to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

7.3 Surface Soil Quality

There are no standards, criteria, or other screening values for assessing potential impacts to terrestrial ecological receptors from contaminants in soils. In addition, the amount of literature data evaluating adverse ecological effects on terrestrial species exposed to contaminants in surface soil is limited and has not undergone extensive peer review.

Toxicological effects on plants and/or invertebrates inhabiting soils contaminated by several of the metals was obtained and compared to the concentrations of these metals. The available data was limited to plants and invertebrates, therefore, effects on mammals, reptiles, birds, and other terrestrial species could not be evaluated. The following paragraphs discuss the comparison of the metals concentrations in the surface soil to published toxicological data.

7.3.1 Site 9

The potential adverse effects on the plants and/or invertebrates from the metals detected at Site 9, were either insignificant or could not be evaluated with the available information.

7.3.2 Site 6 (Lot 201)

The concentration of chromium in some of the surface soil samples exceeded the level that caused mortality in an earthworm species. Therefore, there is a potential risk to at least one earthworm species from the chromium in the surface soils. The potential adverse effects on the plants and/or invertebrates from the other metals detected at Site 6 (Lot 201), were either insignificant or could not be evaluated with the available information.

7.3.3 Site 6 (Lot 203)

The concentrations of chromium, copper, and zinc in some of the surface soil samples exceeded levels that caused adverse effects either to plants or invertebrates. Therefore, there is a potential risk to some plants and/or invertebrates from these metals. The potential adverse effects on the plants and/or invertebrates from the other metals detected at Site 6 (Lot 203), were either insignificant or could not be evaluated with the available information.

7.3.4 Sites 6 (Wooded and Ravine Areas) and 82

The concentrations of arsenic, copper and zinc in some of the surface soil samples exceeded levels that caused adverse effects either to plants or invertebrates. Therefore, there is a potential risk to some plants and/or invertebrates from these metals. The potential adverse effects on the plants and/or invertebrates from the other metals detected at Sites 6 (Wooded and Ravine Areas) and 82, were either insignificant or could not be evaluated with the available information.

7.4 Fish and Crabs

The following sections discuss the current and potential risk to fish and crabs from contaminants identified at OU No.2.

7.4.1 **Population Statistics**

Estuarine fish faunas are typified by the numerical dominance of a few species. The number of estuarine families with basic marine affinities also is small. The dominant species tend to be widespread, reflecting the broad tolerances and range of adaptations of these organisms. By far, the most abundant forms are juveniles that use the estuarine environment as a nursery area. Although a few permanent residents can be found in estuaries at any time, most of the fish populations are seasonal migrants, moving into and out of these shallow ecosystems from the nearshore ocean (Kennish, 1990). Wallace Creek and Bear Head Creek are primarily freshwater in the upper stream areas and brackish in the lower stream areas. The most abundant fish forms found in the creeks were freshwater species.

7.4.1.1 Wallace Creek

The majority of the fish captured in Wallace Creek were freshwater and brackish water species (eastern mosquito, shiner sp., bluespoted sunfish and pumpkinseed). There also were species that typify an estuarine environment (spot, American eel and summer flounder); however, they were not found as abundantly as the freshwater species. The majority of the individuals of those species were represented by the juvenile form and qualify as both seasonal migrants and species that utilize estuaries as a nursery area. The size-class distribution of fish (Figures 4-2 through 4-6) support the presence of a juvenile population.

It should be noted that the population of fish evaluated in Wallace Creek, Bear Head Creek and Pettiford Creek was not large enough to interpret a hypothesis regarding similarity.

The diversity index values ranged from 0.22 at Station 6-WC4 to 0.77 at Station 6-WC6A. Decreased diversity is used as an indicator of gross environmental deterioration, where diversity of taxa and biomass of fish were inversely correlated with the percent of toxic contaminants in a river system. In estuarine environments, the abundance and biomass of fishes are large and the species diversity is generally low. This factor could explain the low diversity at Station 6-WC4.

Overall, the health of the fish community at Wallace Creek appeared normal when compared to the background station at Pettiford Creek. As discussed earlier in this report, none of the fish that were collected had anomalies. A total of four different fish species (Table 4-4) were collected at fish station WC04A (upstream of OU No. 2). The tolerance levels of the species collected are as follows: one intermediate to intolerant species (shiner sp.), one intermediate tolerant species (pirate perch), one moderately tolerant species (pumpkinseed), and one of the species (bluespoted sunfish) has a variable tolerance.

The fish species collected from an adjacent site to OU No. 2 (WC06A) had the following tolerance levels: one intermediate to intolerant species (shiner); three intermediate species (eastern mosquitofish, American eel, and warmouth); one moderately tolerant species (pumpkinseed), one tolerant species (largemouth bass); and two of the species (bluespoted sunfish and sunfish sp.) have variable tolerance levels.

Only one fish species (summer flounder) was collected downstream of OU No. 2 (WC11A) and the tolerance level of this species is not known. The fish species collected from the station adjacent to OU No. 2 were similar in tolerance levels to those species collected upstream of OU No. 2. The only difference in species tolerance between these to stations was that a tolerant species was collected at the adjacent station and no tolerant species were collected at the upstream station.

The majority of the fish that were captured had tolerance levels of intermediate to tolerant, which would indicate that Wallace Creek supports a quality of fish that are tolerant to environmental stressors.

7.4.1.2 Bear Head Creek

The majority of the fish captured in Bear Head Creek were freshwater and brackish water species (eastern mosquito, shiner sp. and pumpkinseed). There also were species that typify an estuarine environment (spot, bay anchovy and killifish); however, they were not found as abundantly as the freshwater species. The majority of the individuals of the estuarine species were represented by the juvenile form and qualify as both seasonal migrants and species that utilize estuaries as a nursery area. The size-class distribution of fish (Figures 4-2 through 4-6) support the presence of a juvenile population.

It should be noted that the population of fish evaluated in Wallace Creek, Bear Head Creek and Pettiford Creek was not large enough to interpret a hypothesis regarding similarity.

The diversity index value for Station 6-BH6A was 0.29. Decreased diversity is used as an indicator of gross environmental deterioration, where diversity of taxa and biomass of fish were inversely correlated with the percent of toxic contaminants in a river system. In estuarine environments, the abundance and biomass of fishes are large and the species diversity is generally low. This factor could explain the low diversity at Station 6-BH6A.

Overall, the health of the fish community at Bear Head Creek appeared normal when compared to the background station at Pettiford Creek. As discussed earlier in this report, none of the fish that were collected had anomalies. Fish were collected at only one station (Table 4-4) in Bear Head Creek BH06A (downstream of OU No. 2). The tolerance of these fish species consisted of the following: one intolerant species (killifish); two intermediate species (eastern mosquitofish and bay anchovy); one moderately tolerant species (pumpkinseed), and one species with variable tolerance (bluespoted sunfish). The majority of the fish species that were captured had intermediate to intolerant levels of tolerance, which would indicate that Bear Head Creek supports a quality of fish that are not tolerant to environmental stressors.

7.4.1.3 Pettiford Creek

Because of the lack of abundance of fish captured at Pettiford Creek, only limited interpretation of the population statistics can be made. The three species of fish that were captured (pumpkinseed, shiner sp. and striped mullet) had tolerances ranging from intolerant to moderately tolerant. The only fish that typified an estuarine environment was the striped mullet. The majority of the individuals of those species were not represented by the juvenile form as in Wallace and Bear Head Creeks. The pumpkinseeds and striped mullet were either above the national average for length or within the top 75 percent of the average.

It should be noted that the population of fish evaluated in Wallace Creek, Bear Head Creek and Pettiford Creek was not large enough to interpret a hypothesis regarding similarity. The diversity index value for Station PC was 0.45. Because of the limited sampling, any hypothesis drawn from this value should not be relied upon.

Overall, the health of the fish community at Pettiford Creek appeared normal. As discussed earlier in this report, none of the fish that were collected had anomalies.

Fish have been collected at one station (Table 4-4) in Pettiford Creek. The tolerance levels of the species collected are as follows: one intermediate to intolerant species (shiner sp.), and one moderately tolerant species (pumpkinseed).

7.4.2 Tissue Analysis

This section summarizes the results of the tissue analysis for the fish and crabs collected in Wallace and Bear Head Creeks, and compares the results to concentrations detected in fish from other studies identified in the literature. Concentrations for some of the contaminants in crab tissues in other studies were not located.

7.4.2.1 Wallace Creek

Fish were collected for tissue analysis at Station 6-WC6A (located adjacent to Site 6) and Station 6-WC11 (located downstream from Site 6) in Wallace Creek. There were no fish collected for tissue analysis from Station 6-WC3A (located upstream from OU No.2) because of inadequate sample size. The following provides the comparison of tissue concentrations of COCs at Wallace Creek to worldwide studies.

Pesticides (4,4'-DDD, 4,4'-DDE and 4,4'-DDT) were detected in all of the fish and crab samples collected in Wallace Creek. These chemicals biodegrade very slowly and they have a high potential for bioaccumulation in aquatic organisms. The maximum concentration of 4,4,'-DDE in the fish tissue was 180 ug/kg and the maximum concentration in the crab samples was 15 ug/kg. The average concentration level established in the National Study of Chemical Residues in Fish (NSCRF) for industrial/urban sites for any p,p'-DDE compound in fish tissue was between 7.23 and 14,028 ug/kg with the mean concentration being 602.34 ug/kg (NSCRF, 1992). Other ecological studies conducted in 1989 in Indonesia on saltwater fish tissues detected levels of p,p'-DDE between 40 and 6,800 ug/kg and 0 to 41 ug/kg in the North Sea (Ginn, 1990). The maximum concentration of 4,4'-DDD in the fish tissue was 8.8 ug/kg and the maximum concentration in the crab samples was 8.1 ug/kg. Studies conducted in Rhode

Island in 1989 detected p,p'-DDD fish tissue levels between 18.0 and 46.0 ug/kg and North Sea studies detected levels between 0 and 28.0 ug/kg (Ginn, 1990). 4,4'-DDT was detected in one fish tissue sample at Station 6-WC6A in the concentration of 4.9 ug/kg. Studies conducted in Pacific ocean revealed levels of 4,4'-DDT ranging from 0 to 76.3 ug/kg (Geesey, 1982). Levels in the Central Mediterranean Sea ranged from 3.9 to 85.5 ug/kg.

Overall, the pesticide levels in the fish tissues at Wallace Creek were within the range of the levels detected in fish from other studies, and the pesticides were at or below levels typical to aquatic life in areas categorized as urban/industrial by the NSCRF. The pesticide concentrations in the fish were higher at Station 6-WC6A as opposed to the downstream Station (6-WC11). There was only one crab submitted for tissue analyses in Wallace Creek. The cause of the slightly elevated pesticide concentrations in the crabs at Station 6-WC11 cannot be attributed directly to OU No. 2 since the crabs are fairly mobile, and the concentrations were not substantially different between the stations. Pesticides were expected to be detected in the fish and crab tissues because pesticide use has been documented as widespread throughout MCB Camp Lejuene, North Carolina.

The concentration of PCBs detected in fish collected from Wallace Creek ranged from 51 to 1,000 ug/kg. The minimum concentration was found at Station 6-WC11 (located downstream from Site 6) and the maximum concentration was found at Station 6-WC6A (located adjacent to Site 6). PCBs were not found in the tissue of the crab. The national average of PCBs found in fish tissue is 1,897 ug/kg (NSCRF, 1992). The NSCRF reported that 91 percent of all the stations included in their survey had PCB contamination. The PCB tissue concentrations found at Wallace Creek were below the reported national average. However, based on the potential sources of contamination at Sites 6 and 82 the PCBs detected in the fish tissue may be attributed to contamination found at Sites 6 and 82.

Toluene was detected in the tissue of fish collected at Stations 6-WC11 and 6-WC6A in the concentrations of 2 ug/kg and 3 ug/kg, respectively. Studies have revealed that the average concentration of toluene in fish collected from a petroleum contaminated harbor in Japan was 5 mg/kg (Howard, 1991). This level of contamination is considerably higher than the levels of toluene found in the fish in Wallace Creek. Toluene does not readily bioaccumulate in fish, and when released into water, it will be lost by both volatilization and biodegradation.

At Stations 6-WC6A and 6-WC11, trichloroethylene was detected in fish tissue at concentrations ranging from 3 to 6 ug/kg. Average concentrations of trichoroethylene in

marine fish in the United States ranged from 0.04 to 1.1 ug/kg in fish tissue, and 0.66 to 20.0 ug/kg in fish livers (Howard, 1991). Therefore, the concentrations of trichloroethylene in the fish tissue collected at Wallace Creek appeared to be at background levels when compared to the national average. It should be noted that trichloroethylene was detected in the surface water and sediments in Wallace Creek. Marine monitoring data suggest only moderate bioconcentration (2 to 25 times the concentration in water). Because of the nature of the potential sources of contamination at Sites 6 and 82 (various solvents), the levels of contamination found in the surface water and sediments, and the bioconcentration factor of trichloroethylene, the trichloroethylene detected in the fish tissue may be attributable to Sites 6 and 82.

Benzene was detected in the fish tissue at Station 6-WC6A and in crab tissue at Station 6-WC11 in concentrations of 3 and 2 ug/kg, respectively. Studies regarding the national average range of benzene in fish and crab could not be located. It is known that benzene is not expected to bioconcentrate in aquatic organisms. This is due in part to benzene's ability to rapidly volatilize when released to water. Because benzene was not detected in either the surface water or sediment in Wallace Creek, it is not likely that the benzene concentrations in the fish could be attributed to Sites 6 and 82.

Phenols were detected in the crab tissue at Station 6-WC11 in the concentration of 2,500 ug/kg. Published studies have indicated that phenols were detected in fish from Commencement Bay, Tacoma, WA in an average concentration of 0.14 ug/kg. The maximum concentration was 0.22 ug/kg (Howard, 1990). The level of phenol in the crab tissue at Wallace Creek was higher than the maximum concentration and the average concentration found in fish at Commencement Bay. However, the sample result was based on a single composite of crab tissue and may not be representative of the entire crab population. Natural sources of phenol include animal wastes and decomposition of organic wastes. Artificial sources of phenols include wastewater from manufacturers of materials such as resins, plastics, iron, steel and rubber. Phenols are frequently found in wastewater from these commercial processes (Sax, 1987). If phenols are released to the environment, its primary removal mechanism is biodegradation which is generally rapid. Data suggest that degradation will take on the order of hours to days in freshwater systems and up to a few weeks in estuarine waters, Also, phenol is not expected to significantly bioconcentrate in aquatic organisms. Phenol was not detected in the surface water of Wallace Creek and was only detected in low concentrations in the sediments. None of the fish tissue samples analyzed from Wallace Creek contained phenols. It is suggested that because of the factors listed above, compounded by the fact that crabs are fairly mobile, phenol cannot be directly attributed to Sites 6 and 82.

Fish tissue concentrations of selenium ranged from 0.14 to 0.38 mg/kg. Worldwide ecological studies detected selenium concentrations in fish tissues from 0.03 to 0.7 mg/kg in Sydney Australia and 0.62 to 14.2 mg/kg in China (Ginn, 1988) and 0.8 to 1.3 mg/kg in Massachusetts (Geesey, 1982). There did not appear to be any difference in selenium concentrations between the fish collected at each station. Therefore, the concentrations of selenium in the fish tissue collected at Wallace Creek appeared to be at background levels when compared to worldwide survey data. Because selenium was not detected in the surface water or sediment samples collected in Wallace Creek, it is unlikely that the selenium concentrations in the fish could be attributed to Sites 6 and 82.

Silver was detected in fish tissues at Station 6-WC6A in the concentration of 0.01 mg/kg. The concentration of silver in the crab tissue at Station 6-WC6A was 0.18 mg/kg. A National Marine Fishery survey conduced in March, 1978 reported the average silver concentration at 0.1 mg/kg in the muscle of the fish and 0.2 mg/kg in the whole body sample of the fish (NOAA, 1978). The tissue samples collected from 6-WC6A appear to be within the reported national average for silver. The maximum bioconcentration factor for silver in fish is 28 (SCDM, 1991). Silver concentrations in exceedence of Region IV Screening Values were found in three Ravine surface water samples. Although silver concentrations were found in Wallace Creek in one surface water sample (6-WC05-SW) and one sediment sample (6-WC03-SD), both of these locations are upstream of ravine sample locations. Wallace Creek sampling stations adjacent to or downstream of the Ravine did not exhibit silver concentrations in surface water or sediments. Therefore, the high silver concentrations found in the Ravine do not appear to be affecting Wallace Creek. The silver exceedence found at sampling station 6-WC05-SW may be a result of tidal influences.

Zinc concentrations in the fish samples ranged from 10.6 to 27.3 mg/kg, while the crab tissue concentration was 20.3 mg/kg. Other saltwater ecological studies detected the following zinc values in fish tissue analyses: 5.9 to 16.6 mg/kg in the Arabian Gulf (Ginn, 1989), 4.1 to 58.8 mg/kg in the Mediterranean Sea in Israel, 0.02 to 5.6 mg/kg in the United Kingdom (Ginn, 1988), and 88 to 145 mg/kg in the Gulf of Mexico (Ginn, 1987). The National Marine Fishery trace element survey revealed that the average concentration of zinc in the muscle of fish ranged from 2.0 to 20.0 mg/kg (NOAA, 1978). It can be determined from the above worldwide data that the concentrations of zinc found in the fish and crabs at Station 6-WC6A were within

the reported normal ranges. Because zinc was detected in higher concentrations in the sediments at the downstream stations as compared to the upstream stations, the zinc detected in the fish tissues may be attributed to contamination from Sites 6 and 82.

The overall physical appearance of the fish, and the relatively low concentration of contaminants present in the fish tissues indicate the aquatic environment at Wallace Creek is not suffering from any stress presented by the detected contaminants; however, some of the contaminants found in the fish tissue (i.e., pesticides, PCBs, trichloroethylene, and zinc) may be attributed to the potential areas of contamination from Sites 6 and 82.

7.4.2.2 Bear Head Creek

Fish were collected for tissue analyses at Station 6-BH6A (located downstream from OU No. 2). There were no fish collected from Station 6-BH4A (located adjacent to OU No. 2) or Station 6-BH2A (located upstream from OU No. 2). The following provides the comparison of tissue analyses at Bear Head Creek to worldwide studies.

Pesticides (4,4'-DDD, 4,4'-DDE and 4,4'-DDT) were detected in the fish sample at Bear Head Creek. These chemicals biodegrade very slow, and as discussed previously in this report, they have a high potential for bioaccumulation in aquatic organisms. The maximum concentration of 4,4,'-DDE in the fish tissue was 290 ug/kg. The average concentration level established in the National Study of Chemical Residues in Fish (NSCRF) for industrial/urban sites for any p,p'-DDE compound in fish tissue was found to be between 7.23 and 14,028 ug/kg with the mean concentration being 602.34 ug/kg (NSCRF, 1992). Other ecological studies conduced in 1989 in Indonesia on saltwater fish tissues detected levels of p,p'-DDE between 40 and 6,800 ug/kg and 0 to 41 ug/kg in the North Sea (Ginn 1990). The maximum concentration of 4,4'-DDD in the fish tissue was 72.0 ug/kg. Studies conducted in Rhode Island in 1989 detected p,p'-DDD fish tissue levels between 18.0 and 46.0 ug/kg; North Sea studies detected levels between 0 and 28.0 ug/kg (Ginn, 1990). 4,4'-DDT was detected in one fish tissue sample at Station 6-BH6A in the concentration of 9.7 ug/kg. Studies conducted in the Pacific ocean revealed levels of 4,4'-DDT ranging from 0 to 76.3 mg/kg (Ginn, 1982). Levels in the Central Mediterranean Sea ranged from 3.9 to 85.5 ug/kg.

Overall, the pesticide levels in the fish tissues at Bear Head Creek were within the range of the levels detected in fish from other studies, and the pesticides are either at, below or slightly above levels typical to aquatic life in areas categorized as urban/industrial by the NSCRF. Pesticides were expected to be detected in the fish tissues because pesticide use has been documented as widespread throughout MCB Camp Lejuene, North Carolina.

The PCB tissue concentration found in Bear Head Creek was reported to be 490 ug/kg. The national average of PCBs found in fish tissue is 1,897 ug/kg (NSCRF, 1992). The NSCRF reported that 91 percent of all the stations included in their survey had PCB contamination. The PCB tissue concentrations found at Bear Head Creek were below the reported national average. However, based on the potential sources of contamination at OU No. 2 (lubricating oil), the PCBs detected in the fish may be attributable to OU No. 2.

Toluene was detected in a fish collected at Station 6-BH6A at a concentration of 8 ug/kg. Studies have revealed that the average concentration of toluene in fish collected from a petroleum contaminated harbor in Japan was 5 mg/kg (Howard, 1991). This level of contamination is considerably higher than the levels of toluene found in the fish in Bear Head Creek. Toluene does not readily bioaccumulate in fish, and when released into water, it will be lost by both volatilization and biodegradation.

Benzene was detected in the fish tissue at Station 6-BH6A in a concentration of 6.0 ug/kg. Studies regarding the national average range of benzene in fish could not be located. It is known that benzene is not expected to bioconcentrate in aquatic organisms (Howard, 1991). This is due in part to benzene's ability to rapidly volatilize when released to water. Benzene was not detected in the surface water in Bear Head Creek; however, it was detected in the sediment at 6-BH1 (located at the most upstream station). Due to the proximity of the positive detection of benzene in the sediment and the lack of detection in surface water, it is not likely that the benzene concentrations in the fish could be attributed to OU No.2.

Fish tissue concentrations of selenium were reported at 0.27 mg/kg. Worldwide ecological studies detected selenium concentrations in fish tissues from 0.03 to 0.7 mg/kg in Sydney Australia and 0.62 to 14.2 mg/kg in China (Ginn, 1988) and 0.8 to 1.3 mg/kg in Massachusetts (Geesey, 1982). The concentrations of selenium in the fish tissue collected at Bear Head Creek appeared to be below the worldwide data. Because selenium was not detected in the surface water in Bear Head Creek and only appeared in one sediment sample, it is unlikely that the selenium concentration in the fish tissue could be attributed to OU No.2.

Cadmium was found in fish tissues at Station 6-BH6A in the concentration of 0.06 mg/kg. The National Marine Fishery trace element survey determined that the national average of

cadmium in fish muscle was less than 0.1 mg/kg (NOAA, 1978); therefore, the concentration of cadmium in the fish tissue collected at Bear Head Creek appears to be below the national average. Cadmium was not detected in the surface water in Bear Head Creek; however it was detected in the sediment in both the upstream and downstream stations. Therefore, the cadmium detected in the fish collected from Bear Head Creek cannot be attributed to contamination from OU No.2.

Zinc concentrations in the fish samples were reported at 23.4 mg/kg. Other saltwater ecological studies detected the following zinc values in fish tissue analyses: 5.9 to 16.6 mg/kg in the Arabian Gulf (Ginn, 1989), 4.1 to 58.8 mg/kg in the Mediterranean Sea in Israel, 0.02 to 5.6 mg/kg in the United Kingdom (Ginn, 1988), and 88 to 145 mg/kg in the Gulf of Mexico (Ginn, 1987). The National Marine Fishery trace element survey revealed that the average concentration of zinc in the muscle of fish ranged from 2.0 to 20.0 mg/kg (NOAA, 1978). It can be determined from the above worldwide data that the concentrations of zinc found in the fish at Station 6-BH6A were within the reported normal ranges. Because zinc was detected in higher concentrations in the sediments at the downstream stations as compared to the upstream stations, the zinc detected in the fish tissues may be attributed to contamination from Sites 6 and 82.

The overall physical appearance of the fish, and the relatively low concentration of contaminants present in the fish tissues indicate the aquatic environment at Bear Head Creek is not suffering from any stress presented by the detected contaminants; however, some of the contaminants found in the fish tissue (pesticides, PCBs, and zinc) could be attributed to the potential areas of contamination.

7.4.2.3 Pettiford Creek

Baker did not collect fish or crab tissue samples at Pettiford Creek.

7.5 <u>Benthic Macroinvertebrate</u>

This section evaluates the current and potential adverse risk to the benthic macroinvertebrates from contaminants detected in the sediments and surface water in Wallace Creek, Bear Head Creek, and the ravine.

7.5.1 Wallace Creek

The species density at Stations 6-WC3A and 6-WC6A was 1,275 and 1,128 individuals/m², respectively and the species diversity for these stations was 0.448 and 0.510, respectively. These values compare to a species density of 210 individuals/m² and species diversity of 0.372 at the Pettiford Creek station (PC). The MBI values at Stations 6-WC3A and 6-WC6A were 6.46 and 7.30, respectively, compared to 8.84 at Station PC.

Station 6-WC3A was more similar to Station 6-WC6A than Station PC concerning water chemistry, habitat, and sediment type. Therefore, the species density, diversity, and MBI values are expected to be similar, if all other factors (i.e., pollution impacts) are equal.

Approximately 74 percent (148 individuals) of the individuals collected at Station 6-WC3A were the chiromid species <u>Tribelos jucundum</u>; none of the other 52 individuals at this station comprised more than six percent of the sample number. <u>Tribelos jucundum</u> does not have a BI, however <u>Tribelos</u> spp. has a BI of 6.6 (Lenat, 1993). <u>Tribelos jucundum</u> is relatively sensitive to heavy metals, and intolerant to organic waters with a tolerance value of 1.0 (U.S. EPA, 1990). This organism is primarily found in freshwaters with salinity concentrations of less than 0.5 ppt and waters having moderate dissolved oxygen concentrations (U.S. EPA, 1977). In addition, they are characteristic of clean water habitats, but are tolerant of organic enrichment if the dissolved oxygen concentration remains above 5.0 mg/l and the pH and water temperature are not adversely altered (U.S. EPA, 1977).

Overall, contaminants at Station 6-WC3A do not appear to be adversely affecting the benthic community based on the similar species densities and diversities between Station 6-WC3A and Station 6-WC6A and the 6.46 MBI value indicating good to fair water quality. In addition, <u>Tribelos jucundum</u>, a relatively intolerant species found primarily in clean environments, accounted for most of the individuals at Station 6-WC3A.

At Station 6-WC6A, approximately 64 percent (113 individuals) of the individuals collected at Station 6-WC6A were the amphipod species, <u>Gammarus fasciatus</u>, 19 percent (34 individuals) were <u>Tribelos jucundum</u>, and 13.5 percent (24 individuals) were the oligochaete species, <u>Limnodrilus hoffmeisteri</u>.

In general, amphipods occur in unpolluted waters (Pennak, 1989). In addition, <u>Gammarus</u> <u>fasciatus</u> (among a few other amphipods) often comprise the majority of specimens taken by casual collectors and widely distributed and common in unpolluted waters (Pennak, 1989). <u>Gammarus fasciatus</u> has a BI of 6.9 (Lenat, 1993) and is facultative in its tolerance to organic wastes with a tolerance value of 2.0 (U.S. EPA, 1990). As discussed above, <u>Tribelos jucundum</u> individuals are usually associated with clean and unpolluted environments. Oligichaetes, however, are generally regarded as "indicators" of organic pollution (Pennak, 1989). <u>Limnodrilus hoffmeisteri</u> has a BI of 9.8 (Lenat, 1993) and is tolerant to organic wastes with a tolerance value of 5.0 (U.S. EPA, 1990).

Overall, contaminants at Station 6-WC6A do not appear to be adversely affecting the benthic community based on the similar species densities and diversities between Station 6-WC6A and Station 6-WC3A and the 7.30 MBI value which indicates fair water quality (Lenat, 1993). In addition, <u>Gammarus fasciatus</u> and <u>Tribelos jucundum</u>, which are generally found in unpolluted environments, comprise approximately 84 percent of the individuals collected at Station 6-WC6A.

No benthic macroinvertebrates were collected at Station 6-WC9A and only eight individuals representing three species were collected at Station 6-WC11A. The dissolved oxygen at these stations were less than 0.2 mg/l at the bottom and there also was a salt wedge at these stations. This most likely accounted for the low density of individuals at these stations because an increase in chemical concentrations were not detected at these two stations. Previous studies have reported that macrobenthos in the deeper mud environments underwent drastic seasonal fluctuations due to anoxic conditions (Tenore, 1972). In addition, the study correlated the absence of benthic life in much of the deeper portions of an estuary with anoxic conditions in those areas (Tenore, 1972).

Several of the metals detected in the surface water of Wallace Creek exceeded their applicable WQSs and/or WQSVs while several of the metals and pesticides and PCB-1260 detected in the sediment of Wallace Creek exceeded their applicable SQSVs. Therefore, although there does not appear to be a current adverse risk to the benthic macroinvertebrate community, the potential for adverse effects to this community is present.

7.5.2 Bear Head Creek

The species density at Stations 6-BH2A and 6-BH4A was 3,709 and 2,747 individuals/m², respectively, and the species diversity for these stations was 0.932 and 0.514, respectively. These values compare to a species density of 210 individuals/m² and species diversity of 0.372

at the Pettiford Creek station (PC). Station 6-BH2A was very similar to Station 6-BH2A based on the water chemistry, habitat, and sediment type, and not very similar to Station PC. The MBI values at Stations 6-BH2A and 6-BH4A were 7.51 and 7.06, respectively, compared to 8.84 at Station PC.

Approximately 45 percent (261 individuals) of the individuals collected at Station 6-BH2A were the oligochaete <u>Isochaetides curvisetosus</u>, 10 percent of the species were the oligochaete <u>Sparganophilus</u> sp., 8 percent of the species were the oligochaete <u>Limnodrilus</u> <u>hoffmeisteri</u>, and 7.5 percent of the species were the bivalve <u>Pisidium casertanum</u>.

As discussed earlier in this report, oligichaetes are generally regarded as "indicators" of organic pollution (Pennak, 1989). However, <u>Isochaetides curvisetosus</u> has a BI of 7.1 (Lenat, 1993), and it is facultative in its tolerance to organic wastes with a tolerance value of 2.0 (U.S. EPA, 1990). A tolerance value for <u>Sparganophilus</u> sp. has not been established. <u>Limnodrilus hoffmeisteri</u> has a BI of 9.8 (Lenat, 1993) and it is tolerant to organic wastes with a tolerance value of five (U.S. EPA, 1990). Finally, <u>Pisidium</u> spp. has a BI of 6.8 (Lenat, 1993) and the species <u>Pisidium casertanum</u> is tolerant to organic wastes with a tolerance value of 4.0 (U.S. EPA, 1990).

Overall, contaminants at Station 6-BH2A do not appear to be adversely affecting the benthic community based on the relatively high species density and diversity values and the MBI value of 7.51 indicating fair water quality (Lenat, 1993). In addition, <u>Isochaetides curvisetosus</u>, a relatively pollution intolerant species found primarily in clean environments, accounted for nearly half of the individuals at Station 6-BH2A.

Approximately 70 percent (301 individuals) of the individuals collected at Station 6-BH4A were the bivalve <u>Pisidium casertanum</u>, 11 percent of the species were the amphipod <u>Gammarus fasciatus</u>, and 8 percent of the species were the oligochaete <u>Limnodrilus</u> <u>hoffmeisteri</u>.

<u>Pisidium casertanum</u>, with a BI of 6.8, and <u>Gammarus</u> <u>fasciatus</u>, with a BI of 6.9 are facultatively tolerant to pollution, while <u>Limnodrilus</u> <u>hoffmeisteri</u>, with a BI of 9.8, is relatively tolerant to pollution.

Overall, contaminants at Station 6-BH4A do not appear to be adversely affecting the benthic macroinvertebrate community based on the similar species densities and diversities between

7 - 23

Station 6-WC3A and Station 6-WC6A and the MBI value of 7.06 indicating fair water quality (Lenat, 1993). The majority of the individuals collected at Station 6-BH4A are facultatively tolerant to pollution, which means they may live in clean or semi-polluted habitats.

One benthic macroinvertebrate was collected at Station 6-BH6A. A slight anaerobic odor was detected in the sediments at Station 6-BH6A indicating that the sediments may have been slightly anoxic. This potentially could have caused the low numbers of individuals at this station.

7.6 <u>Terrestrial Species</u>

As discussed in Section 7.3 (Surface Soil Quality), the contaminant concentrations in the surface soils of a few of the TAL inorganics potentially may be high enough to cause adverse effects to plants or invertebrates (specifically earthworms). The available data was limited to plants and invertebrates, therefore, effects on mammals, reptiles, birds, and other terrestrial species could not be evaluated.

The potential soil exposure to terrestrial fauna at OU No. 2 was evaluated by both direct and indirect exposure to COCs via water and soil and via foodchain transfer. Contaminants of concern at OU No. 2 are identified in section 5.1.3 for each individual site. Indicator species used in this analysis are the whitetailed deer, cottontail rabbit and the quail. The exposure points for these receptors are the surface soils and surface water (surface soils from site 6, Lot 201; Site 6, Lot 203; Sites 6, Wooded areas and Ravine, and 82; and, Site 9; Surface water from Wallace Creek). The routes for terrestrial exposure to the COCs in the soil and water are incidental soil ingestion, drinking water ingestion, and vegetation ingestion.

Total exposure to the COCs in the soil and surface waters by the terrestrial receptors was evaluated by estimating the chronic daily dose and comparing this dose to terrestrial reference values (TRVs) representing acceptable daily dose in mg/kg/day. For this analysis, TRVs were developed from No-Observed-AdverseEffect-Levels (NOAELs) obtained from the Integrated Risk Information System (IRIS, 1993) or toxicological profiles (Table 7-1). No uncertainty factors or modifying factors were applied to the NOAELs.

The estimated chronic daily doses representing the total exposure of the receptors to soils, surface water, and vegetation were determined using the following equation:

$$E = \frac{(Cw)(Iw) + [(Cs)(Bv)(Iv) + (Cs)(Is)][H]}{BW}$$

Where:

E = Total Exposure, mg/kg/d

Cw = Constituent concentration in water, mg/L

Iw = Rate of drinking water ingestion, L/d

Cs = Constituent concentration in soil, mg/kg

Bv = Soil to plant transfer coefficient, unitless

Iv = Rate of vegetation ingestion, kg/d

Is = Incidental soil ingestion, kg/d

H = Contaminated area/Home range area ratio, unitless

BW = Body weight, kg

Bioconcentration of the COCs were calculated using the soil to plant transfer coefficient (Bv) for organics (Travis, 1988) and metals (Baes, 1984). The concentrations of the COCs in the soil, Cs, were the log-normal 95th percentile upper confidence limit of the arithmetic mean concentration and the concentrations of the COCs in the water, Cs, were the log-normal 95th percentile upper confidence limit of the arithmetic mean concentration for Wallace Creek.

The exposure parameters used in the exposure calculation are presented in Table 7-1 and are summarized for each receptor below.

Whitetailed Deer

For the whitetailed deer, the feeding rate is 1.6 kg/d (Dee, 1991). The incidental soil ingestion rate is 0.019 kg/d (Scarano, 1993). The rate of drinking water ingestion is 1.1 L/d (Dee, 1991). The rate of vegetation ingestion is 1.6 kg/d (Dee, 1991). The body weight is 45.4 kg (Dee, 1991), and the home range is 454 acres (Dee, 1991).

Cottontail Rabbit

For the cottontail rabbit, the feeding rate is 0.1 kg/d (Newell, 1987). The incidental soil ingestion rate is 0.002 kg/d (Newell, 1987). The rate of drinking water ingestion is 0.185 L/d

(Federal Register, 1993). The rate of vegetation ingestion is 0.1 kg/d. The body weight is 2 kg (Newell, 1987), and the home range is 10 acres (USDI, 1984).

Bobwhite Quail

For the bobwhite quail, the feeding rate is 0.01 kg/d (Newell, 1987). The incidental soil ingestion rate is 0.001 kg/d (Newell, 1987). The rate of drinking water ingestion is 0.013 L/d (Federal Register, 1993). The rate of vegetation ingestion is 0.01 kg/d. The body weight is 0.1 kg (Newell, 1987), and the home range is 12.1 acres (USDI, 1985).

Estimates of the potential risk to the terrestrial receptors were made by comparing the total exposure of the COCs to the TRVs. Exceedences of the TRVs indicates a potential for adverse effects.

The Quotient Index (QI) method was used in this analysis.

$$QI = \frac{E}{TRV}$$

where:

QI = Quotient Index

E = Total Exposure, mg/kg/day

TRV = Terrestrial Reference Value, mg/kg/day

Ratios of less than unity indicate a low likelihood of adverse effects while a ratio above unity indicate the likelihood of an adverse affect to the receptor. For the COCs that had available TRVs, the QI did not exceed unity for any of the indicator terrestrial receptors.

7.7 Threatened and/or Endangered Species

The only identified threatened or endangered species at OU No. 2 is the American alligator. This species potentially may be adversely affected by the contaminants detected in the surface water, sediments and fish tissue. No attempt was made during this evaluation to estimate the exposure to contaminants in these media because of the large uncertainty in available models. In addition, even if exposure could be quantified, there is limited (if any) toxicological data on alligators. Therefore, actual risk to the alligators exposed to contaminants at OU No. 2 can not be determined.

7.8 <u>Flora/Wetlands</u>

Wetlands have been identified along the banks of Wallace Creek and Bear Head Creek. Wetlands are valuable components of the environment as they play an important role in maintaining and improving environmental quality. A few of their significant functions include controlling flood waters, improving water quality, and providing wildlife habitat.

A wetland delineation or evaluation was not conducted at OU No. 2. Some stressed and/or dead vegetation was observed along the stream bank at a few of the stations. The observed stressed/dead vegetation was neither widespread or extensive in areal extent. This is typical of any wetland system that has natural successional processes occurring including maturing trees and seasonal die off of mature plant species. In addition, natural stresses may be added to the wetlands systems from variation in tidal influence of the saltwater. The National Wetlands Inventory Map (NWI) was examined to determine the classification of wetlands in OU No. 2. The NWI has designated the banks surrounding Wallace Creek as a palustrine system that is forested with evergreens. A palustrine system included all non-tidal wetlands dominated by trees, shrubs, persistent emergents, emergent mosses or lichens, and all such wetlands that occur in tidal areas where salinity due to ocean-derived salts is below 0.5%. The area surrounding Bear Head Creek is also a palustrine system; however, it is forested with primarily deciduous trees. The northern bank is designated as a non-tidal, saturated area, where the southern bank is designated as a non-tidal, temporarily flooded, partially drained area. Contaminants in the surface water and sediments potentially may adversely impact the wetland systems due to the observed exceedences of water and sediment quality values.

7.9 Other Sensitive Environments

Bear Head Creek and the inland portion of Wallace Creek and any coastal wetlands associated with these waters is regulated under the CAMA. The tidal portion of Wallace Creek, and the New River and a 75 foot inland buffer zone are regulated under CAMA. The only activities occurring in the inland portions of the waters that would require authorization under CAMA are activities that would occur in the water (e.g., constructing a pier or boat ramp, dredging, etc.). In addition, for the tidal waters, any land disturbing activities (e.g., construction, digging, etc.) within the water and within the 75 feet buffer zone will require a permit or authorization. OU No. 2 is located in the inland portion of Bear Head Creek and Wallace Creek. There do not appear to be any activities that will occur in the waters at these locations, and therefore no authorization under CAMA would be required.

No specific areas within Wallace Creek, Bear Head Creek, and the New River directly downstream of Wallace Creek have been designated as spawning areas critical for the maintenance of fish/shellfish, however, some spawning areas may exist in these waters. The potential impacts to the fish in these waters have already been discussed in this report. These same impacts would apply to fish in the spawning areas. The fish/shellfish in these spawning areas, however, may be more susceptible to chemical stresses due to the higher sensitivity of the reproductive life stages of organisms to these types of stresses.

The Wallace Creek Swamp Natural Area is located in and adjacent to Wallace Creek upstream of Piney Green Road. Although this area is upstream of the suspected sources of contamination at OU No. 2, potential impacts to this area may occur if contaminants are transported upstream due to the tidal influence in Wallace Creek.

No specific areas with Wallace Creek, Bear Head Creek, and the New River directly downstream of Wallace Creek have been designed as nursery areas, however, some nursery areas may exist in these waters. The potential impacts to the fish in these waters have already been discussed in this report. These same impacts would apply to fish in the nursery areas. The fish/shellfish in these spawning areas, however, may be more susceptible to chemical stresses due to the higher sensitivity of juvenile organisms to these types of stresses.

7.10 <u>Uncertainty Analysis</u>

The procedures used in this evaluation to assess risks to ecological receptors, as in all such assessments, are subject to uncertainties. In general, the following are the main sources of uncertainty:

- Environmental chemistry sampling and analysis;
- Environmental parameter measurement;
- Exposure parameter estimation;
- Toxicological information.

Each of these sources of uncertainty as they pertain to this risk assessment are discussed below.

The chemical sampling program at OU No. 2 consisted of surface water, sediments, soil, tissue, and groundwater. The concentrations of chemicals in the surface water will vary with the tides; the concentrations are expected to be lower at higher tides (more dilution) and higher at low tides (less dilution).

The proximity of estuaries to landmasses renders them highly susceptible to pollution from human activities; this pollution threatens fish communities in many regions. Anthropogenic stresses on fish populations can be intense. Whereas much attention has been focused on the acute exposure of these populations to pollutants, sublethal and chronic exposures also debilitate resident and seasonal species. The mobility and migratory habits of fishes, however, make observations on anthropogenic effects more difficult to assess, and most of the evidence on pollution-induced changes in fish populations has been derived from laboratory experiments. Effects of man-made stresses on fishes in estuaries are often obscured by naturally occurring and poorly understood, long-term variations.

The ecological investigation consisted of one sampling effort. The results of this sampling will only provide a "snapshot in time" of the ecological environment. Because the biotic community can have a high amount of natural variability, the "snapshot in time" may not be an accurate representation of actual site conditions. There also is error and uncertainty in the sampling methods used to collect the fish and benthic macroinvertebrates. Because few, if any, fish were collected at the stations, the population statistics were not reliable. In addition, in several of the tissue samples, only one fish was analyzed because only one was collected of that species. Therefore, the concentrations of contaminants may not be a good representation of the average tissue concentration.

The collection of benthic macroinvertebrates has less uncertainty than the collection of fish. However, the effectiveness of the ponar depends upon the sediment type. The ponar is less effective in hard, rocky sediments, or sediments with a lot of organic debris that may prevent the ponar from completely closing, than in soft, mucky sediments. Because the sediment types varied among the stations, the effectiveness of the ponar also would have varied.

There is uncertainty in trying to attribute differences in species density, diversity, and similarities between stations to specific hazards, because these differences may be the result of

natural causes. As discussed previously, fish and crabs are mobile. Therefore, the tissue contaminant concentrations cannot be correlated with the contaminants detected at OU No. 2 because the fish or crabs may have been exposed to the contaminants at a different location. Also, as observed in this investigation, natural conditions (salt wedge, low dissolved oxygen) can result in low numbers of individuals.

There also is uncertainty in the use of toxicological data in ecological risk assessments. The surface water and sediment values established by North Carolina and Region IV are set to be protective of a majority of the potential receptors. There will be some species, however, that will not be protected by the values because of their increased sensitivity to the chemicals. Also, the toxicity of chemicals mixtures is not well understood. All the toxicity information used in the ERA for evaluating risk to the ecological receptors is for individual chemicals. Chemical mixtures can affect the organisms very differently than the individual chemicals.

Finally, estuaries are physically unstable areas characterized by large spatial and temporal variations in temperature, salinity, oxygen concentration, turbidity, and other factors. Temporally, such variations take place in the short term and long term. Yet, despite these variations, the basic structure of estuarine fish communities is reasonably stable, and the fishes often have more or less predictable patterns of abundance and distribution. However, estuarine fish populations change dramatically in response to environmental perturbations; these population changes can be permanent even though the predominantly estuarine species have broad temperature tolerances and strong osmoregulatory abilities. The species composition of estuarine communities change constantly, attesting to the variable environmental conditions and the limitations of the tolerances of the fish populations to alterations in the habitat.

7.11 Ecological Significance

The objective of the ERA was to determine if past reported disposal practices at OU No. 2 were adversely impacting the ecological integrity of the terrestrial environment or of Wallace Creek, Bear Head Creek, or the ravine. The ecological significance of the results is necessary to provide the risk managers with the requisite information, to be used in conjunction with the human health risk assessment, in order to determine the appropriate remedial action at the site for the protection of public health and the environment. For the aquatic portion of the ERA, the results indicate that COCs present in surface water and sediments of Wallace Creek, Bear Head Creek, and the Ravine could pose a moderate to high potential risk to aquatic receptors. The presence of VOCs in Wallace Creek results from groundwater discharge from the site to the creek. However, none of the TCL organic chemicals detected in the surface water samples exceeded the WQS or WQSV values. Some TAL inorganics exceeded the WQS and/or WQSV in both creeks and the ravine. However, although the ravine is a source of the inorganic contamination, the results of the inorganic sampling in Wallace Creek could not establish a direct impact to the creek due to exceedence of these inorganics in both upstream and downstream samples. The fish population of both creeks appeared healthy and population statistics did not indicate that they were impacted by COCs from OU No. 2. Fish tissue results indicated that some COCs were elevated in concentration and could be attributed to sources of COCs at OU No. 2. The primary influence on the benthic macroinverebrate community appeared to be related to the presence of salinity gradients in the two creeks. The salt wedge that developed at the interface of the freshwater and saltwater systems resulted in low dissolved oxygen that created an adverse habitat for intolerant species. It is noted that the seasonal rainfall for the area was atypically high and resulted in lower salinities throughout the New River estuary.

For the terrestrial portion of the ERA, the results indicate that COCs present in the surface soils could pose a moderate risk to plant and terrestrial invertebrates when compared to available toxicological values. However, comparisons of the total exposure to the COCs in the soil and surface waters by the terrestrial vertebrate receptors with available TRVs indicated that the QI did not exceed unity for any of the indicator terrestrial receptors.

Based on the above findings, past reported disposal practices at OU No. 2 potentially are adversely impacting the ecological integrity of Wallace Creek, Bear Head Creek, or the ravine. The findings do not indicate a potentially adverse impact to vertebrate terrestrial receptors.

8.0 SUMMARY/CONCLUSIONS

The following sections contain the summary/conclusions for the ERA including Water Quality, Sediment Quality, Surface Soil Quality, fish and benthic macroinvertebrates.

8.1 <u>Water Quality</u>

The water quality summary/conclusions are discussed in the following sections.

8.1.1 Wallace Creek

None of the TCL organic COCs detected in Wallace Creek exceeded applicable water quality criteria values. Dissolved oxygen concentrations and pH values were below WQS and WQSV at some of the stations, but probably were associated with natural conditions.

Surface water concentrations of cadmium, copper, lead, mercury, nickel, silver, and zinc exceeded the North Carolina Water Quality Standards (WQS) and/or U.S. EPA Region IV acute or chronic Water Quality Screening Values (WQSV) in some of the samples. The exceedences of these TAL inorganics occurred in upstream and/or downstream samples or were infrequent in occurrence.

In addition, several TAL inorganics had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in Wallace Creek to be adversely affected by chronic toxicity from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represents long-term conditions.

8.1.2 Bear Head Creek

None of the TCL organic COCs detected in Bear Head Creek exceeded applicable water quality criteria values. Dissolved oxygen concentrations and pH values were below WQS and WQSV at some of the stations, but probably were associated with natural conditions.

Surface water concentrations of copper, lead, mercury, nickel, and silver exceeded the WQS and/or WQSV in some of the samples. The exceedences of these TAL inorganics occurred in upstream and/or downstream samples or were infrequent in occurrence.

In addition, several TAL inorganics had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in Bear Head Creek to be adversely affected by chronic toxicity from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represents long-term conditions.

8.1.3 Ravine

None of the TCL organic COCs detected in the ravine exceeded applicable water quality criteria values.

Surface water concentrations of aluminum, cadmium, copper, iron, lead, silver, and zinc exceeded the WQS and/or WQSV in some of the samples. The exceedences of these TAL inorganics occurred in upstream and/or downstream samples or were infrequent in occurrence.

In addition, several TAL inorganics had the ratio of the upper 95% confidence limit (or maximum value) and the chronic WQSV greater than unity. Based on these results, the potential risk for aquatic life in the ravine to be adversely affected by chronic toxicity from the COCs in the surface water is expected to be moderate to high, provided that the exposure concentration evaluated represents long-term conditions.

8.1.4 Pettiford Creek

Dissolved oxygen concentrations were below the WQS at one station, but probably was associated with natural conditions.

8.2 <u>Sediment Quality</u>

The sediment quality summary/conclusions are discussed in the following sections.

8.2.1 Wallace Creek

Sediment concentrations of copper, lead, silver, zinc, 4,4'-DDE, 4,4'-DDD, 4,4'-DDT, dieldrin, PCB-1260, benzo(a)pyrene, fluoranthene, and pyrene exceeded the Region IV lower 10 percentile (ER-L) and/or median percentile (ER-M) sediment screening values (SQSV) in some

8-2

of the samples. The exceedences of the TAL inorganics occurred in both upstream and downstream samples and, therefore, do not appear site related. Dieldrin was detected in the uppermost station only. The remaining pesticides and PCBs exceeded the SQSV primarily in adjacent and downstream samples and their presence might be attributable to site runoff. The PAHs only were detected near roadways.

In addition, several TAL inorganics and TCL organics had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in Wallace Creek to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

8.2.2 Bear Head Creek

Sediment concentrations of lead, 4,4'-DDE, 4,4'-DDD, 4,4'-DDT, PCB-1260, and benzo(a)pyrene exceeded the ER-L and/or ER-M SQSVs in some of the samples. The exceedences of lead occurred in both upstream and downstream samples and, therefore, do not appear site related. The pesticides and PCBs exceeded the SQSV primarily in adjacent and downstream samples and their presence might be attributable to site runoff. The PAHs exceeded the SQSV near the roadway only.

In addition, several TAL inorganics and TCL organics had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in Bear Head Creek to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

8.2.3 Ravine

Sediment concentrations of cadmium, lead, mercury, silver, zinc, 4,4'-DDE, 4,4'-DDD, 4,4'-DDT, dieldrin, endrin, PCB-1260, and several PAHs exceeded the ER-L and/or ER-M SQSVs in some of the samples. These constituents probably are attributable to site runoff.

In addition, several TAL inorganics and TCL organics had the ratio of the upper 95% confidence limit and the ER-L greater than unity. Based on these results, the potential risk for aquatic life in the ravine to be adversely affected by chronic toxicity from the COCs in the sediments is expected to be moderate to high.

8.3 Surface Soil Quality

The surface soil quality summary/conclusions are discussed in the following sections. The effects on terrestrial life from pesticides, PCBs, PAHs and several of the metals could not be addressed in the ERA because of lack of available information. The following paragraphs discuss effects on terrestrial life from the metals for which toxicological information was found.

8.3.1 Site 9

None of the metals detected in the Site 9 surface soil for which toxicological information was available, exceeded the applicable values.

8.3.2 Site 6 (Lot 201)

Surface soil concentrations of chromium detected at Site 6 (Lot 201) exceeded published toxicological values and potentially may cause adverse effects to terrestrial life.

8.3.3 Site 6 (Lot 203)

Surface soil concentrations of chromium, copper and zinc detected at Site 6 (Lot 203) exceeded published toxicological values and potentially may cause adverse effect to terrestrial life.

8.3.4 Sites 6 (Wooded and Ravine Areas) and 82

Surface soil concentrations of arsenic, copper, and zinc detected at Sites 6 (Wooded and Ravine Areas) and 82 exceeded published toxicological values and potentially may cause adverse effects to terrestrial life.

8.4 <u>Fish</u>

The fish summary/conclusions are discussed in the following sections. 8.4.1 Population Statistics

The summary/conclusions for the fish population statistics are discussed in the following sections.

8.4.1.1 Wallace Creek

The majority of the individuals collected at Wallace Creek were represented by juveniles representing the following species: eastern mosquito, shiner sp., pumpkinseed and the american eel.

Community similarity indices showed the greatest similarity between Stations 6-BH6A and 6-WC6A (0.53) and the least similarity between Stations 6-BH6A and 6-WC11 (0) and Stations 6-WC4 and 6-WC11 (0). Because a limited number of fish were collected at all the stations, the similarity values are not reliable.

The diversity of fishes collected at Wallace Creek varied within the stations. Typically, estuarine environments produce a high biomass and abundance, but are limited in the quantity of species. As with the similarity values, the diversity values are not representative of the creek due to the limited data set.

At Wallace Creek, there were no anomalies observed on the fish such as lesions, bacterial or viral infections.

The fish community at Wallace Creek appeared healthy and the population statistics did not indicate that the environment was impacted by contaminants of concern from OU No. 2.

8.4.1.2 Bear Head Creek

The majority of the individuals collected at Bear Head Creek were represented by juveniles which included, eastern mosquito, spot, and pumpkinseed.

Community similarity indices showed the greatest similarity between Stations 6-BH6A and 6-WC6A (0.53) and the least similarity between Stations 6-BH6A and 6-WC11 (0) and Stations 6-WC4 and 6-WC11 (0). Because a limited number of fishes were collected at all the stations, the similarity values are not reliable.

The diversity value derived from the fish collected at Bear Head Creek was 0.29. Typically, estuarine environments produce a high biomass and abundance, but are limited in the

quantity of species. As with the similarity values, the diversity values are not representative of the creek due to the limited data set.

At Bear Head Creek, there were no anomalies observed on the fish such as lesions, bacterial or viral infections.

The fish community at Bear Head Creek appeared healthy and the population statistics did not indicate that the environment was impacted by contaminants of concern from OU No. 2.

8.4.1.3 Pettiford Creek

The individuals collected at Pettiford Creek included, shiner sp., pumpkinseed, and striped mullet. Because of the limited numbers of fishes that were collected, conclusions regarding population were limited.

The only diversity value derived from the fish collected at Pettiford Creek was 0.45. Typically, estuarine environments produce a high biomass and abundance, but are limited in the quantity of species.

At Pettiford Creek, there were no anomalies observed on the fish such as lesions, bacterial or viral infections.

The fish community at Pettiford Creek appeared healthy and the population statistics did not indicate that the environment was impacted by contaminants.

8.4.2 Tissue Analysis

The summary/conclusions for the fish tissue analysis are discussed in the following sections.

8.4.2.1 Wallace Creek

Toluene, silver, benzene, and selenium were detected in fish and crab tissue samples. The fish tissue concentrations were within the range of tissue concentrations for these contaminants reported in ecological studies. Because of the frequency of detection of these contaminants both upstream and downstream from OU No. 2, the contaminants can not be attributed to the sites.

The fish community at OU No. 2 had elevated tissue concentrations of the following contaminants of concern: pesticides, PCBs, trichloroethene, and zinc. Due to the nature of the contaminants of concern, these constituents may be attributed to OU No. 2. The crab tissues had elevated levels of phenols, although the contaminant can not be attributed to the site.

8.4.2.2 Bear Head Creek

Toluene, cadmium, benzene and selenium were detected in fish and crab tissue samples. The fish tissue concentrations were within the range of tissue concentrations for these contaminants reported in ecological studies. Because of the frequency of detection of these contaminants both upstream and downstream from OU No. 2, the contaminants can not be attributed to the sites.

The fish community in Bear Head Creek had elevated tissue concentrations of the following contaminants of concern: pesticides, PCBs, and zinc. Due to the nature of the contaminants of concern, these constituents may be attributed to OU No. 2.

8.4.2.3 Pettiford Creek

Baker was not tasked with collecting fish for tissue analysis at Pettiford Creek.

8.5 Benthic Macroinvertebrate

The benthic macroinvertebrate summary/conclusions are discussed in the following sections.

8.5.1 Wallace Creek

Species richness in Wallace Creek was highest in the upstream stations (7-12 species) and lowest in the downstream stations (0-3 species). Species density followed a similar pattern with approximately 1,200 individuals/m² in the upper reaches and approximately 50 individuals/m² in the lower reaches of the creek. Species diversity was less than 0.5 at all the sampled stations on Wallace Creek.

The dominant species in the creek varied from the chiromid species <u>Tribelos jucundum</u> (74 percent of the individuals) in the upper reaches, the amphipod <u>Gammarus fasciatus</u> (64

percent of the individuals) in the mid-reaches, and the polychaetes <u>Nereis succinea</u> and <u>Capitella capitata</u> (five of the eight individual) and the oligochaete <u>Limnodrilus hoffmeisteri</u> (three of the eight individuals) in the lower reaches of Wallace Creek. This variation followed the variation in salinity measurements at the stations and indicated the effects of the tidal influence seen in the transition from a freshwater system in the upper reaches of the creek and the estuarine influence in the lower reaches of the creek.

The Macroinvertebrates Biotic Index (MBI) ranged from good-fair (6.46) in the upper reaches of the creek to poor (9.8) in the lower reaches of the creek. However, the salinity gradient influenced the species composition in the lower reaches with the tolerant freshwater oligochaete species being present. In addition, the presence of the salt wedge and low dissolved oxygen can create an adverse habitat for intolerant species.

8.5.2 Bear Head Creek

Species richness in Bear Head Creek was highest in the upstream stations (16-33 species) and lowest in the downstream station (one species). Species density followed a similar pattern with approximately 2,700 to 3,700 individuals/m² in the upper reaches and approximately 25 individuals/m² in the lower reaches of the creek. Species diversity was less than 1.0 at the upper reach station and less than 0.5 in the mid-reach station. Only one species was found in the lower reach station.

The dominant species in the creek varied from the oligochaete species <u>Isochaetides</u> <u>curvisetosus</u> (45 percent of the individuals) in the upper reaches, the bivalve <u>Pisidium</u> <u>casertanu</u> (70 percent of the individuals) in the mid-reaches, and the polychaete <u>Nereis</u> <u>succinea</u> (100 percent of the individuals) in the lower reaches of Bear Head Creek. This variation followed the variation in the salinity measurements at the stations and indicated the effects of the tidal influence seen in the transition from a freshwater system in the upper reaches of the creek and the estuarine influence in the lower reaches of the creek.

The MBI was poor and ranged from 7.51 in the upper reaches of the creek to 7.06 in the midreach of the creek. However, the salinity gradient influenced the species composition in the lower reach with no freshwater species being present. In addition, the presence of the salt wedge and low dissolved oxygen can create an adverse habitat for intolerant species.

8-8

Although there was no observed salt wedge or salinity graident in Bear Head Creek between the biological sampling stations (i.e., above station 6-BH07), Table 3-4 does indicate that a salinity gradient and salt wedge exists at station 6-BH07SW/SD, approximately 2,500 feet below station 6-BH07. Table 3-18 indicates that surface water samples were taken at station 6-BH07-SW/SD on a falling tide approximately 80 percent to low tide. Finally, there are reported large fluctuations in salinity in estuaries similar to the New River watershed (e.g., White Oak River) with measured salinities varying by 10 to 15 ppt at a given station. Due to the high seasonal rainfall, the salt wedge may be positioned much lower in the downstream reach of Bear Head Creek than would be typical. Therefore, a salinity gradient is the likely influence in the species composition in the lower reach of the creek.

8.5.3 Pettiford Creek

Four species were collected in Pettiford Creek and species density was 210 individuals/m². Species diversity was less than 0.5 at the sampled station on Pettiford Creek. The dominant species in the creek was the oligochaete <u>Limnodrilus hoffmeisteri</u> (70 percent of the individuals). The MBI was poor at 8.84.

8.6 <u>Terrestrial Receptors</u>

Total exposure to the COCs in the soil and surface waters by the terrestrial receptors was evaluated by estimating the chronic daily dose and comparing this dose to terrestrial reference values (TRVs). Indicator species used in this analysis were the whitetailed deer, cottontail rabbit and the quail. The exposure points for these receptors are the surface soils and surface water (surface soils from site 6, Lot 201; Site 6, Lot 203; Sites 6, Wooded areas and Ravine, and 82; and, Site 9; Surface water from Wallace Creek). The routes for terrestrial exposure to the COCs in the soil and water are incidental soil ingestion, drinking water ingestion, and vegetation ingestion. Estimates of the potential risk to the terrestrial receptors were made by comparing the total exposure of the COCs to the TRVs using the Quotient Index (QI) method. Ratios of less than unity indicate a low likelihood of adverse effects while a ratio above unity indicate the likelihood of an adverse affect to the receptor. For the COCs that had available TRVs, the QI did not exceed unity for any of the indicator terrestrial receptors.

8.7 Ecological Significance

The objective of the ERA was to determine if past reported disposal practices at OU No. 2 were adversely impacting the ecological integrity of the terrestrial environment or of Wallace Creek, Bear Head Creek, or the ravine. The ecological significance of the results is necessary to provide the risk managers with the requisite information, to be used in conjunction with the human health risk assessment, in order to determine the appropriate remedial action at the site for the protection of public health and the environment.

Based on the above findings, past reported disposal practices at OU No. 2 potentially are adversely impacting the ecological integrity of Wallace Creek, Bear Head Creek, or the ravine. The findings do not indicate a potentially adverse impact to vertebrate terrestrial receptors. Adriano, D.C. 1986. <u>Trace Elements in the Terrestrial Environment</u>. Springer-Verlag New York Inc.

SPECIAL NOTE This document was prepared primarily by stereoscopic analysis of high altitude aerial photographs. Weilands were identified on the photographs based on vegetation visible hydrology and geography in accordence with Classifica-tion of Wetlands and Degowards Mathematica Statistics states (FMS/QBS + JW/3) Decomber 1979) The serial states to based to reduce the serial this document

Federal State and local regulatory agencies with jurisdie Federal State and local regulatory sgencies with jurisdic-tion over wellands may define and describe wetlands in a different manner than that used in this inventory. There is no attempt, in either the design or products of this inven-tory, to define the limits of programy jurisdiction of any Federal. State or local government or to establish the geographical scope of the regulatory programs of govern-ment agencies. Persons intending to engage in activities involving modifications within or adjacent to wetland areas should seek the advice of appropriate Federal. State or local agencies concerning specified agency regulatory programs and proprietary jurisdictions that may affect such activities.

- **R20WH** (LINEAR DEEPWATER HABITAT)

NOTES TO THE USER

IN IERMITENT STREAMS) may not devert the dewite ton of wetland. This map uses the class Unconsolidated Shore (US) On earlier NWI maps that class was designated Beach/ Bar (BB), or Flat (FL) Subclasses remain the same in both

APPENDIX B MCB CAMP LEJEUNE ENDANGERED SPECIES AND SPECIAL INTEREST COMMUNITIES SURVEY Critical species list - Camp Lejeune endangered species and <u>special-interest communities survey</u>

مرارية مريحان معود المحمد والمنتجر المريحات المحاصرة والمحاصر المحاجر وراعدات المتعامر والتربع مراري معقات فيمريهم

Principal investigator: Richard LeBlond, 326-1440 (******************************

List current as of 9-30-91. Replaces list of 6-30-91.

"?" = Species names followed by a "?" are less than confidently identified. They are nonetheless caught in this biological safety net, the mesh size of which errs on the side of diversity. Until identification is confirmed (most of these are represented by a specimen), these site records should be regarded as tentative.

Species sites are listed chronologically under the species name; with the 1990 month and day of discovery listed first, followed by the site's sector site number, community type and UTM grid number. Sites documented prior to the start of the current survey are indicated by the parenthetical date of discovery following the site name (see <u>Rhexia aristosa</u> at FD-1). Prior sites not yet relocated during the current survey are indicated by "---" in the date column (see <u>Rhynchospora tracyi</u> at FD-1).

Status codes. Federal status is listed first, and separated from the state status by a comma; e.g., <u>Rhexia</u> <u>aristosa</u> FC2,T (Federal Candidate level 2, state Threatened). Species with state status only are indicated by a single code without comma; e.g., <u>Rhynchospora</u> tracyi SR (Significantly Rare).

FE = Federal Endangered

FT = Federal Threatened

FC1 = Federal Candidate level 1. At risk. Listing warrented but precluded by higher priorities.

FC2 = Federal Candidate level 2. Vulmerable. Listing warrented but precluded by higher priorities.

F3C = Federal Candidate level 3C. More abundant and/or less threatened than previously known.

- E = State Endangered
- T = State Threatened
- SC = State Special Concern
- C = State Candidate
- SR = State Significantly Rare
- W =State Watch List (W1)
- W3 = " " " , undocumented state occurrence prior to Lejeune site.

proposed = proposed for listing as State Candidate, Significantly Rare or Watch List based on current evidence List of species and communities by sector - Camp Lejeune endangered species and special-interest communities survey

List current as of 9-30-91. Replaces list of 6-30-91.

NATURAL AREA DESCRIPTION - WALLACE CREEK SWAMP CAMP LEJEUNE MARINE CORPS BASE, ONSLOW CO.

(from Moore 1985)

NAME OF SITE: Wallace Creek Swamp. RB-2 (portions of the area also occur in Sectors FA and RA).

QUAD: Camp Lejeune. UTM COORDINATES: 882417.

LOCATION AND DIRECTIONS: Wallace Creek floodplain east from Old Piney Green Road for 0.9 mile, and extending 0.3 mile north in floodplain of North Prong Wallace Creek flowing southward from Powerline Road 0.9 mile east of Piney Green Road. Site includes portions of Compartment 7 timber stand 7, Compartment 8 timber stand 11, and Compartment 20 timber stand 2.

SIZE: 115 acres. PROVINCE: Coastal Plain. WATERSHED: Wallace Creek / New River.

GENERAL LANDSCAPE DESCRIPTION: Broad floodplain and former mill pond on Wallace Creek dominated by a Cypress-Gum Swamp community (CT-1) grading upstream into a Coastal Plain Small Stream Swamp community (CT-2). The adjacent uplands contain mixed pine/ hardwood communities, including Loblolly Pine associations with Red Oak and Sweet Gum.

PHYSICAL DESCRIPTION

ASPECT: Flat. SLOPE: Flat. TOPOGRAPHIC POSITION: Alluvial flats. HYDROLOGY: Palustrine. MOISTURE: Wet to intermittently flooded. SOILS: Muckalee loam (CT-1, CT-2) grading to Marvyn loamy fine sand on the low slopes. GEOLOGY: Talbot surface unconsolidated sandy sediments. ELEVATION: <5-5 feet (CT-1), 5-10 feet (CT-2).

NATURAL COMMUNITY DESCRIPTION - CT-1

A) NAME OF COMMUNITY: Cypress-Gum Swamp.

B) VEGETATION STRUCTURE: <u>Taxodium</u> canopy and open understory over an herbaceous ground layer.

C> DOMINANTS AND IMPORTANT SPECIES: Canopy: <u>Taxodium distichum</u> dominates, with a subcanopy of <u>Nyssa biflora, Acer rubrum, Ulmus alata and Fraxinus</u> pennsylvanica. C) DOMINANTS AND IMPORTANT SPECIES:

Shrub layer: scattered <u>Sabal minor</u> and <u>Persea palustris</u>. Ground layer: grass dominated with <u>Glyceria striata</u>, <u>Poa</u> spp., <u>Panicum</u> spp.

D) POSITION IN THE LANDSCAPE AND RELATION TO OTHER COMMUNITIES: Community occupies a former mill pond basin grading upstream into the small stream swamp community (CT-2).

E) QUALITY AND CONDITION: Community dominated by old Cypress trees 5 or more feet in diameter at their bases, and 2-2.5 feet in diameter 6-7 feet above ground. Community occurs within a former mill pond basin and thus is artificially influenced.

F) SIZE: Estimated at 90 acres.

NATURAL COMMUNITY DESCRIPTION - CT-2

A) NAME OF COMMUNITY: Coastal Plain Small Stream Swamp (Blackwater Subtype).

B) VEGETATION STRUCTURE: Mixed Cypress-hardwood canopy with moderate understory over a patchy herbaceous ground layer.

C) DOMINANTS AND IMPORTANT SPECIES:

Canopy: <u>Taxodium distichum</u>, <u>Nyssa biflora</u>, <u>Fraxinus</u> <u>pennsylvanica</u>, <u>Ulmus americana</u>, <u>Acer rubrum</u>, <u>Liquidambar</u> <u>styraciflua</u>. <u>Taxodium</u> is not as dominant here as in the Cypress--Gum community.

Understory: Persea palustris, Sabal minor, Ilex opaca.

D) POSITION IN THE LANDSCAPE AND RELATION TO OTHER COMMUNITIES: Community occurs in the floodplain upstream from the former mill pond Cypress-Gum Swamp community (CT-1) and grades at the low slope into upland pine/hardwood communities.

E) QUALITY AND CONDITION: Apparently a typical example with mature forest.

F) SIZE: Estimated at 25 acres.

SPECIAL STATUS SPECIES PRESENT PLANTS

NC: <u>Ponthieva</u> <u>racemosa</u> (CT-1).

POTENTIAL FOR OTHER SPECIAL STATUS SPECIES: Moderate; site not visited during current survey, but contains suitable habitat for <u>Carex chapmanii</u> and <u>Scirpus lineatus</u>.

OTHER NOTEWORTHY SPECIES OR FEATURES PRESENT: State Watch List species: <u>Dryopteris ludoviciana</u> (CT-1) and <u>Senecio glabellus</u> (CT-1), which also may occur in CT-2.

SITE INTEGRITY: Site impacted by creation and discontinuance of mill pond.

AVERAGE DBH OF CANOPY TREES CT-1: No information available. CT-2: No information available. MAXIMUM DBH OF CANOPY TREES CT-1: <u>Taxodium distichum</u> - 2-2.5 feet. CT-2:

FIRE REGIME: Site not on a controlled burn rotation; communities not fire dependent.

OTHER DISTURBANCES OR IMPACTS: None known (but see next item).

ADJACENT LAND USE: Upland area south of the floodplain from Old Piney Green Road to ca. 0.3 mile east has been heavily impacted as part of the Engineer Training Area, and is the site of a proposed landfill.

SIGNIFICANCE OF SITE: The old-growth Cypress stand in the old mill pond is a rare remnant of a once-common community.

PROTECTION CONSIDERATIONS AND MANAGEMENT NEEDS: Landfill site needs to be monitored to insure that erosion, debris and pollution do not enter the Wallace Creek drainage system.

SURVEY BOUNDARIES: Stream channels surveyed eastward to Smith Road and northward to highway NC 24 (by J.H. Moore and/or S. Leonard in 1984).

PRIORITY FOR FURTHER STUDY: The small stream swamp community (CT-2) needs additional survey work to determine extent, quality and special status species present.

OTHERS KNOWLEDGEABLE ABOUT SITE: S. Leonard, J.H. Moore.

PLANT SPECIES LIST

Codes: D = stratal dominant or codominant; d = subdominant; * = special status species; x = present.

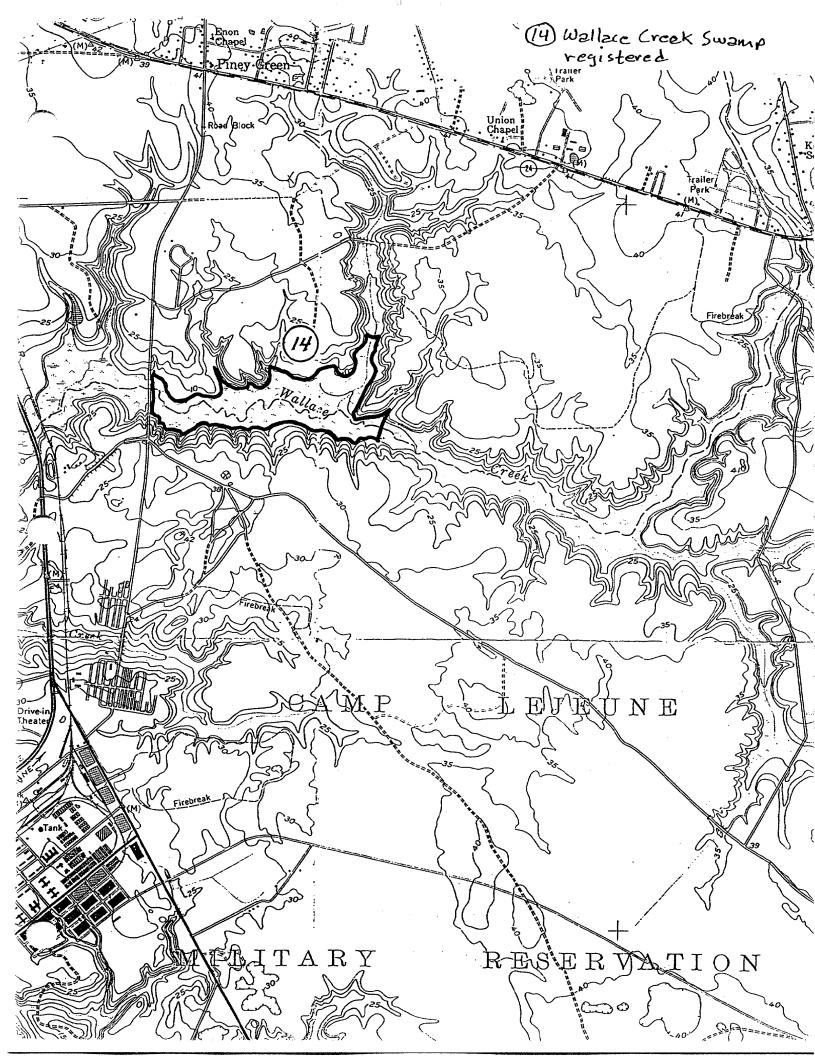

CT-1: Cypress-Gum Swamp. CT-2: Coastal Plain Small Stream Swamp (Blackwater Subtype).
